Draft Version 6

Science and Adaptive Management Plan

Missouri River Recovery Program

Draft/Pre-decisional/For Review and Comment

December 2016

The U.S. Army Engineer Research and Development Center (ERDC) solves
the nation's toughest engineering and environmental challenges. ERDC develops
innovative solutions in civil and military engineering, geospatial sciences, water
resources, and environmental sciences for the Army, the Department of Defense,
civilian agencies, and our nation's public good. Find out more at www.erdc.usace.army.mil.

To search for other technical reports published by ERDC, visit the ERDC online library

8 Prepared for U.S. Army Corps of Engineers
9 Washington, DC 20314-1000

10 Under Missouri River Recovery Program

1 **Abstract:** The Missouri River Recovery Program (MRRP) is undergoing a
2 transformation resulting from 2011 recommendations by an Independent Science
3 Advisory Panel and the Missouri River Recovery Implementation Committee (MRRIC).
4 An Effects Analysis study established the best available scientific information and
5 provided the foundation for an Adaptive Management Plan (AM Plan) that addresses
6 lingering uncertainties and improves management decisions while implementing
7 actions that avoid jeopardizing the three federally listed species in the system. This
8 draft AM Plan includes a process for resolving critical uncertainties using a framework
9 consisting of four implementation levels: 1) research, 2) in-river testing of hypotheses,
10 3) scaled implementation of select management actions, and 4) full implementation.
11 The decision criteria for moving to higher levels of implementation are included. A
12 NEPA evaluation of alternative management actions identified an initial suite of actions
13 that will be implemented to meet the objectives of the MRRP. This Draft AM Plan
14 accompanies the Draft Missouri River Recovery Management Plan-Environmental
15 Impact Statement and provides the roadmap for the implementation of the selected
16 alternative and for the identification of subsequent management needs should the
17 initial suite of actions fail to meet objectives. The AM Plan will be implemented
18 collaboratively by the U.S. Army Corps of Engineers, the U.S. Fish and Wildlife Service,
19 and MRRIC following the governance process outlined in the AM Plan.

Table of Contents

2	List of Figures and Tables	xi
3	Preface.....	xix
4	Unit Conversion Factors	xxi
5	1 Introduction.....	1
6	1.1 Overview, background and context	1
7	1.1.1 Overview	1
8	1.1.2 Missouri River Recovery Program (MRRP)	2
9	1.1.3 Purpose and scope of the MRRP	8
10	1.1.4 Effects Analysis (EA) and modeling framework for the MRRP	9
11	1.1.5 AM and decision-making concepts	12
12	1.1.6 Relationship between MRRMP-EIS alternatives and actions in the AM Plan.....	13
13	1.2 Adaptive Management (AM) governance.....	16
14	1.2.1 AM decision needs.....	16
15	1.2.2 Program composition, roles, and responsibilities	18
16	1.2.3 AM decision process.....	20
17	1.2.4 Protocols and procedures	23
18	1.2.5 Other key points and issues	23
19	1.3 AM for plovers and terns.....	23
20	1.3.1 Bird objectives, uncertainties, and targets.....	24
21	1.3.2 Implementing, monitoring, and evaluating bird actions	27
22	1.3.3 Decisions and planning contingencies.....	31
23	1.3.4 Other key points or issues	33
24	1.4 AM for pallid sturgeon.....	33
25	1.4.1 Overview of Chapter 4	34
26	1.4.2 Pallid sturgeon objectives and key uncertainties.....	34
27	1.4.3 Pallid sturgeon framework	37
28	1.4.4 Pallid sturgeon in the Upper Missouri River	38
29	1.4.5 Pallid sturgeon in the Lower Missouri River	41
30	1.5 Human Considerations (HC)	44
31	1.5.1 How HCs are considered	45
32	1.5.2 Monitoring and assessment of HCs.....	45
33	1.5.3 Further considerations	46
34	1.6 Data acquisition, management, reporting and communications.....	46
35	1.6.1 Monitoring and other data acquisition issues.....	47
36	1.6.2 Data management.....	47
37	1.6.3 Reporting and communications.....	48
38	1.6.4 Quality assurance (QA) and quality control (QC)	49
39	1.7 Summary	49
40	2 Governance of the AM Program.....	53
41	2.1 Definition, principles and key attributes for effective governance	53

1	2.1.1	Governance defined.....	53
2	2.1.2	Attributes of governance that enable AM.....	53
3	2.1.3	Ensuring objective and reliable science in the Missouri River Recovery Program ..	56
4	2.2	Decision needs for adaptively managing the MRRP	58
5	2.2.1	Scope of decisions in the MRRP	59
6	2.2.2	Balancing needs for the birds and fish.....	62
7	2.2.3	Timing of AM decisions.....	63
8	2.2.4	Role of decision criteria in the MRRP	66
9	2.2.5	NEPA, the Master Manual, and decisions regarding management actions.....	67
10	2.3	AM program composition, roles, and responsibilities	68
11	2.3.1	Oversight level.....	73
12	2.3.2	Management Team.....	75
13	2.3.3	Implementation-Level Teams.....	78
14	2.3.4	Technical Team.....	83
15	2.3.5	Integrated Science Program (ISP).....	85
16	2.3.6	Other MRRP entities and position descriptions	87
17	2.3.7	Overview of MRRIC roles and responsibilities	91
18	2.3.8	Basin states, other Federal agencies, and tribal roles outside the MRRIC collaborative process	102
19	2.4	AM Decision process, critical engagements, and workflows	105
20	2.4.1	Overview of the MRRP AM decision process.....	105
21	2.4.2	Basic Annual AM engagement process.....	106
22	2.4.3	Science Update process.....	110
23	2.4.4	WP development and approval	117
24	2.4.5	Consideration of new management actions.....	120
25	2.4.6	Workflows for specific scenarios.....	124
26	2.5	Important protocols and procedures	145
27	2.5.1	Procedures for dispute resolution.....	146
28	2.5.2	Procedures for changing the governance of the MRRP AM Program.....	148
29	2.5.3	Procedures for adjusting objectives, targets, or decision criteria.....	149
30	2.5.4	Procedure for addressing significant new information.....	150
31	2.5.5	Procedures for elevating and relegating hypotheses	152
32	2.5.6	Independent external review.....	153
33	2.5.7	Requirements for research and focused study efforts	155
34	2.5.8	Agendas for the Fall Science Meeting and for the Annual AM Workshop	156
35	2.5.9	Guidelines for technical publications.....	156
36	2.5.10	Example Fact Sheet	157
37	2.5.11	Cultural Resource Plan	157
38	2.5.12	Program priorities development process	157
39	2.5.13	Cost management.....	158
40	2.5.14	Program safety and health requirements	161
41	3	Adaptive Management for Plovers and Terns	162
42	3.1	Assess.....	162
43	3.1.1	Management objectives and scope for least terns and piping plovers	162
44	3.1.2	Key findings from Effects Analysis (EA)	167
45	3.2	Plan and Design	177

1	3.2.1	<i>Bird Framework</i>	177

19	Figure 41. Schematic of decision space using flow management for ESH creation	180
20	Figure 42. ESH characterization. a) Available ESH is measured at the maximum July flow (blue outline)	
21	observed in that year. Standardized ESH is observed at the same flow (dashed line) each year. b)	
22	Standardized ESH measures changes in sandbars due to erosion from an earlier year (dark profile) to a	
23	later year (light profile). c) Available ESH area may increase from one year to next if flows are lower, even	
24	though standardized ESH area decreases from erosion and vegetation growth.....182	
25	Figure 43. Shoreline habitat characterization. a) Available shoreline is measured as the difference	
26	between the maximum elevation inundated >160 days in the previous 2 years (dotted line) and the	
27	elevation inundated on May 15 th of the current year (solid outline). b) If the elevation inundated on May	
28	15 th is higher than the maximum elevation inundated >160 years, the available shoreline metric = 0 ft. c)	
29	The inundation metric is the change in elevation between May 15 th (dashed line) and August 3 rd (solid line)	
30	and may be a positive number if water levels increase (shown) or a negative number if water levels	
31	decrease (not shown). ..184	
32	Figure 44. Anticipated range of “effective” combinations of flow and duration that meet standardized	
33	acreage targets given initial ambient ESH, with presumed “decision space” shown for Gavins Point and	
34	Garrison reaches.....211	
35	Figure 45. Standardized (squares) and available acreage exceedance targets (circles) with confidence	
36	bounds (light blue squares, dashed lines). Observed habitat acreages can fall within four numbered	
37	regions relative to the acreage bounds, as described in the text.....237	
38	Figure 46. Observed standardized ESH (blue line) from 2006-2014 relative to targets (median, solid black	
39	line; 95% confidence interval, dashed lines) for a) the Northern region and b) the Southern region. Green	
40	circles indicate years that the time frame of 3 out of 4 years exceeding the median target is met.239	
41	Figure 47. Observed exceedance of available ESH (blue) from 2006-2015 relative to target exceedance	
42	distributions (median, solid black line; 95% confidence interval, dashed lines) for a) the Northern region	
43	and b) the Southern region. Circles indicate the 75%, 50%, 25% and 10% exceedance criteria specified in	
44	the targets. Note that only 10 years of data are available; a 12-year rolling window of data will be used	
45	once 12 years of data are available. The observed exceedance meets the median targets for habitat	
46	availability if the blue line is to the right of the solid black line..... 240	

1	Figure 48. Metrics of available shoreline (solid gray lines, high values are good), inundation during the nesting season (dashed black line, low values are good) and observed fledge ratios (blue circles) for a) Lake Sakakawea and b) Lake Oahe. Fledge ratios on reservoirs were not estimated in 2013.	241
4	Figure 49. The relationship between reservoir habitat metrics (available shoreline and inundation) and whether the fledge ratio target of 1.14 is met (filled shapes) or not met (unfilled shapes) for a) Lake Sakakawea and b) Lake Oahe for 1993-2014. Recent years are highlighted in blue (fledge ratios were not estimated on reservoirs in 2013). Note that some labels have been omitted for legibility. The dotted line indicates combinations of the two metrics predicted by the model to meet the fledge ratio targets; data points above and to the left of the line are expected to meet the targets and data points below and to the right of the line are not.	242
11	Figure 50. Plover population growth rate ($\lambda = N_t/N_{t-1}$) (green) and fledge ratio (blue) annual values (thin lines), 3-year running geometric mean of growth rate (thick green line) and 3-year running average fledge ratio (thick blue line) from population monitoring 1998-2015 for a) the Northern Region and b) the Southern Region. Years with especially low and high population growth rate (2011-2012; dotted lines) reflect the effect of high flows that did not allow breeding in 2011. As few nesting birds were observed in 2011, calculated population growth reflects the absence then return of birds to nesting areas in addition to changes in population size due to reproduction and mortality. Dashed lines indicate targets.	244
18	Figure 51. Hypothetical comparison of projected population sizes under a management scenario (blue lines) with a population trajectory that meets the target (black line). Solid lines are median values of 5,000 model replicates; dashed lines are 95% confidence intervals.	245
21	Figure 52. Evaluation of status over time for a) plover fledge ratio (gray lines) and population growth rate (black lines) and b) plover population size. Symbol color indicates status relative to status and needs matrix (see Table 356 for definitions.)	249
24	Figure 53. Example of an evaluation of key relationships. Results of best-fit model relating plover density to fledge ratio in annual assessment of density dependence in plover population. Points indicate fledge ratios in individual reaches and years, solid line is median prediction of model, dashed lines are 95% confidence intervals.	252
28	Figure 54. Example of model validation for 2005-2013 for a) standard ESH and b) available ESH modeled using predicted flows (validation type 2 above) and c) plover adults and d) tern adults using predicted ESH (validation type 4 above). Solid black lines indicate the median prediction of 5,000 model replicates; dashed black lines indicate the 95% confidence interval. Thick blue lines are observations.	257
32	Figure 55. Model projections of a) standard acres and b) adult plovers for two hypothetical management options, compared to a target trajectory and doing nothing. Solid lines are median results of 5,000 model replicates. Dashed lines are 95% confidence intervals.	262
35	Figure 56. Diagnostic decision tree for a) determining why bird targets are not being met, and b) identifying recommended corrective actions.	271
37	Figure 57. Historical range and present-day occupancy of the pallid sturgeon and scope of the Missouri River included in the EA. Present day occupancy shown on the right side map includes the stretch of the river above Gavins Point Dam and below Fort Randall Dam, which is not included in the defined area of the Lower Missouri River. Pallid sturgeon may be found in reservoirs but do not prefer these habitats. Source: Figure 2 in Jacobson et al. 2016a.	282
42	Figure 58. Map of the upper (A) and lower (B) river complex, showing the Yellowstone and Missouri Rivers, major tributaries, and reservoirs. Black lines are absolute barriers; gray lines are likely barriers, including run of river weirs.	283

25	Table 43. Summary of time limits for implementation and scope of actions.....	312
26	Table 44. Overview of highest priority Level 1 and 2 science components for the Upper Missouri, anticipated to be completed within the first five years of the Record of Decision (ROD) (subject to budget and resource constraints). Appendix C contains a complete list of all Level 1 and 2 components, and Appendix F describes the prioritization process. Components listed in Appendix C but not in this table could be implemented beyond the 5-year, post-ROD period. Metrics and decision criteria with associated degrees of certainty for the working management hypotheses are summarized from Appendix C. Categories for Degree of Certainty: 1 = Definitive, 2 = Statistically rigorous, 3 = Indicative but not authoritative, 4 = Expert judgment of multiple lines of evidence required. BQ = Big Question, L = Level, C = Component (e.g., BQ1/L1/C2 is Big Question 1, Level 1, Component 2). Work under BQ6 subject to Recovery Team discussions and Propagation Strategy. Hypotheses are from Table 1 in Jacobson et al. 2016a.	316
36	Table 45. Overview of highest priority Level 1 and 2 science components for the Lower Missouri, anticipated to be completed within the first five years of the Record of Decision (ROD) (subject to budget and resource constraints). Appendix C contains a complete list of all Level 1 and 2 components, and Appendix F describes the prioritization process. Components listed in Appendix C but not in this table could be implemented beyond the 5-year post-ROD period. Metrics, and decision criteria with associated degrees of certainty for the working management hypotheses are summarized from Appendix C. Categories for Degree of Certainty: 1 = Definitive, 2 = Statistically rigorous, 3 = Indicative but not authoritative, 4 = Expert judgement of multiple lines of evidence required, BQ = Big Question, L = Level, C = Component. (e.g., BQ1/L1/C2 is Big Question 1, Level 1, Component 2). Work under BQ6 subject to Recovery Team discussions and Propagation Strategy. Hypotheses are from Table 1 in Jacobson et al. 2016a.	321

Preface

2 This report presents the draft Adaptive Management Plan (AM Plan) for the Missouri
3 River Recovery Program (MRRP). Further revision of this document is planned. A
4 finalized draft will be submitted along with the draft Missouri River Recovery
5 Management Plan-Environmental Impact Statement (MRRMP-EIS) in 2017.

6 The purpose of this draft is not to convey a determined suite of actions for adaptive
7 management (AM) but rather to present AM concepts, methods and decision criteria
8 that might be employed in the final AM plan. Alternative suites of actions and
9 associated research are being evaluated under the National Environmental Policy Act
10 (NEPA) as part of the MRRMP-EIS. The outcome of the NEPA process will be a
11 selected alternative which, in conjunction with Endangered Species Act (ESA) Section 7
12 consultation outcomes, will constitute the actions for immediate implementation.

13 The authors have utilized the actions included in the draft EIS (DEIS) to illustrate the
14 concepts, methods and decision criteria necessary to an AM Plan for the MRRP. These
15 actions include those proposed in Planning Aid Letters (PALs) from the U.S. Fish and
16 Wildlife Service (USFWS). Discussion of these actions in this draft report does not
17 constitute selection of any potential actions; their inclusion is merely to help
18 demonstrate how AM might be implemented for various actions. The final AM Plan
19 will be based on the selected alternative in the Record of Decision.

20 Some details regarding the AM Program will be determined or refined through ongoing
21 interactions with the agencies, stakeholders, and independent reviewers. Recognizing
22 these limitations, it is intended that this draft provides sufficient insight into the scope
23 and nature of the MRRP AM Plan that reviewers can fairly evaluate the plan, offer
24 constructive comments and engage in discussions regarding improvements to be
25 incorporated into the final AM Plan.

26 We gratefully acknowledge the many people who contributed to this draft. We used
27 materials from previous drafts and contributions to sections of this draft by Robb
28 Jacobson of the USGS and the Pallid Sturgeon EA Team; Mark Harberg, Dan Pridal,
29 Aaron Quinn, Clayton Ridenour, Mary Roth and Randy Sellers of the USACE Omaha
30 District; Todd Gemeinhardt of the USACE Kansas City District; Doug Latka of the
31 USACE Missouri River Division; Tom St. Clair of Louis Berger and Associates; and
32 Natascia Tamburello of ESSA. Technical content was provided by Casey Kruse, Wayne
33 Nelson-Stastny, and Carol Smith of the USFWS, and technical reviews and comments
34 were provided by Chantel Cook, Coral Huber, Brad Thompson, and Tim Welker of the
35 USACE; Wyatt Doyle, Rob Holm, Steven Krentz, Landon Pierce, Dane Schuman and

1 Ryan Wilson of the USFWS; David Adams, Justin Haas, Gerald Mestl and Kirk
2 Steffensen of the Nebraska Game and Parks Commission; the Upper Bain Pallid Work
3 Group; Michelle Klose, on behalf of a consortium of state representatives; and several
4 members of the AM ad hoc Task Group and MRRIC members at large. Assistance in
5 developing input to the report by Paul De Morgan of Resolve, particularly in
6 incorporating concepts for governance, is gratefully acknowledged.

19	USGS	U.S. Geological Survey
20	WG	Work Group
21	WP	Work Plan
22	WRDA	Water Resources Development Act
23		

1 **Glossary**

2

3 **Accounts** –Human Considerations objectives and performance criteria are organized
4 into four accounts in accordance with U.S. Army Corps of Engineers Planning
5 Guidelines. The four accounts are as follows:

- 6 • Environmental Quality (EQ)
7 • National Economic Development (NED)
8 • Regional Economic Development (RED)
9 • Other Social Effects (OSE)

10

11 **Active adaptive management** – The active form of adaptive management (AM)
12 employs management actions in an experimental design aimed primarily at learning to
13 reduce uncertainty; near-term benefits to the resource are secondary.

14 **Adaptive action** – A course of action to be implemented as defined in the Adjust step
15 (Step 5b of the AM process) if the performance of a particular management action is
16 not as anticipated and requires correction. In cases where the action is pre-defined, it is
17 referred to as a “contingency action.”

18 **Adaptive Management (AM)** – Adaptive management is a decision process that
19 promotes flexible decision making that can be adjusted in the face of uncertainties as
20 outcomes from management actions and other events become better understood.
21 Careful monitoring of these outcomes advances scientific understanding and helps
22 adjust policies or operations as part of an iterative learning process.

23 **Alternatives** –A specified combination of management actions that collectively are
24 deemed to meet minimum performance levels for the endangered species. In the
25 Problem Definition, Objectives, Alternatives, Consequences, Tradeoffs (PrOACT)
26 process, the trade-offs associated with various alternatives on multiple interests are
27 explored in order to find the alternative(s) that minimize unnecessary negative impacts
28 and is/are otherwise thought to be the “best balance” of impacts on a wide range of
29 interests. Alternatives are used to address the objectives.

30 **AM Report** – Annual or periodic report that documents new learning based on
31 monitoring results, evaluates progress towards meeting species objectives, and contains
32 recommendations for adjustments to management actions. The Annual AM Report is
33 contained with the Annual Report on Biological Opinion (BiOp) compliance.

- 1 **Annual Work Plan (AWP)** – This document includes real estate actions, habitat
2 creation actions, monitoring of physical and biological responses to actions, and
3 research activities for a particular year within the five-year Strategic Work Plan. It is
4 used by product delivery teams to budget and implement management actions
5 annually.
- 6 **Biological Assessment (BA)** – A document prepared for the Section 7 process to
7 determine whether a proposed major construction activity under the authority of a
8 Federal action agency is likely to adversely affect listed species, proposed species, or
9 designated critical habitat.
- 10 **Biological Opinion (BiOp)** – Document stating the U.S. Fish and Wildlife Service
11 (USFWS) and the National Marine Fisheries Service (NMFS) opinion as to whether a
12 Federal action is likely to jeopardize the continued existence of a threatened or
13 endangered species or result in the destruction or adverse modification of critical
14 habitat. Specifically in the MRRP, the USFWS 2000 Biological Opinion (BiOp) found
15 that the operation of the Missouri River Mainstem Reservoir System (System) and the
16 operation and maintenance of the Missouri River Bank Stabilization and Navigation
17 Project (BSNP), as proposed by the USACE, would likely jeopardize the continued
18 existence of three federally listed species: the piping plover, least tern, and pallid
19 sturgeon. The BiOp was amended in 2003 to note that, with additional actions
20 proposed by the USACE, operation of the System and the operation and maintenance of
21 the BSNP would not likely jeopardize terns and plovers, but would jeopardize pallid
22 sturgeon. In this document, the amended BiOp is referred to as the USFWS 2003
23 Amended Biological Opinion.
- 24 **Conceptual Ecological Models (CEMs)** – CEMs are graphical depictions of an
25 ecosystem that are used to communicate the important components of the system and
26 their relationships. They are a representation of the current scientific understanding of
27 how the system works.
- 28 **Contingency action** – A pre-evaluated adaptive action that is implemented when
29 triggered by defined decision criteria without the need for further deliberation or
30 decision.
- 31 **Critical uncertainties** – Uncertainties that impede the identification of a preferred
32 alternative management action.
- 33 **Critical Engagement Point (CEP)** – Specific points in the formulation or
34 implementation phases of adaptive management when the agencies engage with the

- 1 Missouri River Recovery Implementation Committee (MRRIC) for input. These can be
2 concurrent with, or in addition to, routine MRRIC plenary meetings.

- 3 **Decision context** – Involves defining what decision (question or problem) is being
4 made, why it is being made, and also describing the scope of the playing field (bounds)
5 for the management decision as well as its relationship to other decisions previously
6 made or anticipated.

- 7 **Decision criteria** – Broadly refers to the set of pre-determined criteria used to make
8 AM decisions. Performance metrics, targets, and decision triggers are considered to be
9 different types of decision criteria. They can be qualitative or quantitative based on the
10 nature of the performance metric and the level of information necessary to make a
11 decision.

- 12 **Decision space** – A term used to characterize a range of operational discretion for
13 flows (or potentially other actions) that is “acceptable” to stakeholders, effective in
14 achieving objectives, and within the bounds of actions evaluated under NEPA.
15 Management actions would generally occur within this region, and any operation
16 outside this decision space would require further coordination and approval.

- 17 **Decision trigger** – Decision triggers are pre-defined commitments (population or
18 habitat metric for a specific objective) that trigger a change in a management action.
19 Decision triggers are addressed in the Evaluate step (Step 4 of the AM process)
20 specifying the metrics and actions that will be taken if monitoring indicates
21 performance metrics are or are not reaching target values. In some cases, a decision
22 trigger may be learning a new piece of information that triggers the
23 Continue/Adjust/Complete step (Step 5 of the AM process).

- 24 **Delphi process** – The Delphi process is a method of eliciting expert opinion
25 (Normand et al. 1998). While many variations of the process exist, there are generally
26 three common features: (1) qualified experts provide their responses to a set of
27 questions in a structured format; (2) the answers to these questions are synthesized
28 across all respondents and presented back to the same set of experts; and (3) the
29 experts jointly discuss the reasons for variation in the first set of responses (or lack
30 thereof), and through dialogue potentially revise their opinions. A modified Delphi
31 process was applied by Jacobson et al. (2016b) to prioritize candidate hypotheses.

- 32 **Effects Analysis (EA)** – The purpose of this effort is to conceptually and quantifiably
33 make explicit the effects of operations and actions on the listed species by specifically
34 evaluating the effects of hydrologic and fluvial processes on the Missouri River, as well

- 1 as ongoing management actions under the USFWS 2003 Amended Biological Opinion
2 and other Mitigation actions, on the status and trends of the listed species (piping
3 plover, interior least tern, and pallid sturgeon) and their habitats.
- 4 **Environmental Impact Statement (EIS)** – A document which summarizes and
5 analyzes environmental impacts of a proposed action and alternatives.
- 6 **Evaluation** – Conduct analyses to compare measured results with anticipated
7 outcomes related to decision criteria for specific management actions to determine
8 whether the implementation should be continued, adjusted, or completed.
- 9 **Event-driven reporting cycle** – In addition to the annual and periodic AM reports
10 (on a routine reporting schedule), reporting may also be event- driven, where new
11 observations or data resulting from an unforeseen event suggest a decision trigger or
12 targets have been reached.
- 13 **First increment** – The suite of proposed actions evaluated in the Management Plan/
14 EIS that are anticipated to be implementable in the foreseeable future (~10 – 15 years).
15 The First Increment will include actions for pallid sturgeon for Levels 1 through 3 of the
16 Lower Pallid Framework to ensure NEPA coverage for future implementation.
- 17 **Formal consultation** - The consultation process conducted when a Federal agency
18 determines its action may affect a listed species or its critical habitat, and is used to
19 determine whether the proposed action may jeopardize the continued existence of
20 listed species or adversely modify critical habitat. This determination is stated in the
21 Service's biological opinion.
- 22 **Fundamental objectives** – Fundamental objectives are used to formalize the desired
23 outcome of the program in terms of biological response. They are derived to achieve
24 avoidance of jeopardizing the three species from USACE actions on the Missouri River
25 and articulate the ends the program is trying to achieve.
- 26 **Global hypotheses** – Set of possible, biologically important hypotheses, relevant to
27 population dynamics that are derived from conceptual ecological models.
- 28 **Human Considerations (HCs)** – A set of objectives with associated metrics and
29 proxy metrics that are related to the wide array of uses and stakeholder interests on the
30 Missouri River. They form the basis for some of the monitoring and decision criteria in
31 the AM Plan.

1 **Hypotheses reserve** – A concept that seeks to explicitly manage the broad suite of
2 hypotheses developed through the (EA) and highlighted in the CEM. In this concept
3 hypotheses can be brought forward or moved back into reserve as information and
4 understanding directs. The hypotheses reserve concept includes (1) hypotheses that
5 are not deemed important to investigate at this time, (2) have high uncertainty and
6 require further investigation, and/or (3) are outside USACE authority.

7 **Initially modeled hypotheses** – Subset of working management hypotheses
8 determined by the USACE to be within jurisdiction and applicable authorities, and
9 therefore selected for modeling in Phase 1 of the (EA).

10 **Integrated Science Program (ISP)** – The component of the MRRP that is
11 responsible for conducting scientific monitoring and investigations. The ISP monitors
12 federally listed species under the Endangered Species Act (ESA), the habitats upon
13 which they depend, and researches and monitors critical uncertainties.

14 **Interests (interest area)** – In MRRIC, the interest areas are categories of values that
15 people have said are important (e.g., agriculture, hydropower, cost).

16 **Implement** – Implementation of the selected alternative.

17 **Implementation level (or Level)** – Refers to one of four classifications of action
18 that could be implemented to assist pallid sturgeon as part of the MRRP (see also *Pallid*
19 *Sturgeon Framework*). The levels include the following:

- 20 • **Level 1: Research** – Studies without changes to the system (laboratory studies or
21 field studies under ambient conditions).
- 22 • **Level 2: In-river testing** – Implementation of actions at a level sufficient to
23 expect a measurable biological, behavioral, or physiological response in pallid
24 sturgeon, surrogate species, or related habitat response.
- 25 • **Level 3: Scaled implementation** – A range of actions not expected to achieve
26 full success, but which yields sufficient results in terms of reproduction, numbers,
27 or distribution to provide a meaningful population response and indicate the level
28 of effort needed for full implementation.
- 29 • **Level 4: Ultimate required scale of implementation** – Implementation to
30 the ultimate level required to remove an issue.

31 **Investigations** – Research activities that are intended to generate information that
32 will fill the key gaps in understanding and reduce uncertainty associated with
33 implementation of management actions.

1 **Jeopardy** – As defined by the Endangered Species Act (ESA), jeopardy occurs when
2 there is an action that reasonably would be expected, directly or indirectly, to reduce
3 appreciably the likelihood of both the survival and recovery of a listed species in the
4 wild by reducing the reproduction, numbers, or distribution of that species.

5 **Limiting factor** – A factor that controls the growth, abundance, or distribution of an
6 organism. For example, factors that limit the survival of terns, plovers, and pallid
7 sturgeon have been identified and serve to identify and organize potential management
8 actions.

9 **Lower Missouri River** – The reach of the river downstream of Gavins Point Dam
10 (RM 810) as it pertains to management for pallid sturgeon.

11 **Management actions** – Proposed or potential actions to be taken by the USACE to
12 address species needs on the Missouri River. Management actions were prescribed by
13 the USFWS 2003 Amended Biological Opinion as Reasonable or Prudent Alternatives
14 or actions outside the BiOp if necessary to achieve species objectives.

15 **Management hypotheses** – Statements (in affirmative hypothesis form) that a
16 specific management action will be effective in eliminating factors that are thought to
17 be limits to population growth.

18 **Missouri River Recovery Management Plan (MRRMP; also MRRMP-EIS or
19 Management Plan)** – A suite of management actions that avoids jeopardizing the
20 continued existence of piping plovers, interior least terns, and pallid sturgeon, thereby
21 permitting the continued operation of the Missouri River reservoir System and the
22 Bank Stabilization and Navigation Program (BSNP). It includes actions proposed by
23 the Missouri River Recovery Implementation Committee, and complies with the
24 National Environmental Policy Act (NEPA) and other statutory mandates, regulatory
25 requirements, and authorizations. MRRMP may also refer to the 3-year process to
26 programmatically evaluate the MRRP and develop a suite of actions that meet ESA
27 responsibilities. The Management Plan or MRRMP-EIS are umbrella terms that
28 include the MRRMP, the Environmental Impact Statement (EIS), and the AM Plan.

29 **Means objectives** – Describe ways of achieving the fundamental objectives and
30 specify the way and degree to which the fundamental and sub-objectives can be
31 achieved. They are used to further develop management actions and alternatives and
32 are potentially useful in tracking progress towards fundamental objectives in the near-
33 term when a response in the fundamental objectives may not be detectable in shorter
34 time frames due to a delayed species response to management actions or other reasons.

1 **Monitoring** – In the context of the MRRP AM Plan, monitoring is the process of
2 measuring attributes of the ecological, social, or economic system. Monitoring has
3 multiple purposes, including: to provide a better understanding of spatial and temporal
4 variability, to confirm the status of a system component, to assess trends in a system
5 component, to improve models, to confirm that an action was implemented as planned,
6 to provide the data used to test a hypothesis or evaluate the effects of a management
7 action, and to provide an understanding of a system attribute that could potentially
8 confound the evaluation of action effectiveness.

9 **MRRP Adaptive Management Plan** – The purpose of this Adaptive Management
10 (AM) Plan is to describe a formal AM process led by the USACE and USFWS in
11 implementing the Missouri River Recovery Program (MRRP or Program).

12 **National Environmental Policy Act (NEPA)** – Requires Federal agencies to
13 integrate environmental values into their decision-making processes by considering the
14 environmental impacts of their proposed actions and reasonable alternatives to those
15 actions. To meet NEPA requirements, Federal agencies may be required to prepare an
16 EIS.

17 **Naturalization of the flow regime** – Naturalization of the flow regime involves
18 incremental changes that move the flow regime towards the hydrological attributes that
19 would exist in the absence of dams and reservoirs, while recognizing social and
20 economic constraints. It does not mean matching the unaltered, historical flow regime.
21 Generally, naturalization refers to the process of using characteristics of the natural
22 ecosystem to guide elements of river restoration, but constrained by social and
23 economic values (Rhoads et al. 1999; Jacobson and Galat, 2008).

24 **No-action alternative** – When addressing on-going programs, the Council on
25 Environmental Quality defines no action as “no change” from current management
26 direction or level of management intensity. The MRRP No Action Alternative,
27 therefore, may be thought of as continuing with the courses of action being executed at
28 the time the Notice of Intent for the EIS was published.

29 **Objectives** – Objectives define an endpoint of concern and the direction of change
30 that is preferred. Objectives are concise statements of the interests that could be
31 affected by a decision — the “things that matter” to people. In PrOACT, objectives
32 typically take a simple form such as minimize costs and increase population number,
33 increase habitat availability.

- 1 **Pallid sturgeon framework**— An organization of Missouri River pallid hypotheses
2 that allows for the description of activities (research to management actions), decision
3 criteria, uncertainty, risk, impacts, costs, time frame, and constraints.
- 4 **Passive adaptive management** – In passive AM, management actions are focused
5 on achieving resource objectives; development of knowledge through monitoring and
6 assessment for improved decision making is secondary.
- 7 **Performance metric** – A specific metric or quantitative indicator that is monitored and
8 can be used to estimate and report consequences of management alternatives with respect
9 to a particular objective. There are specific species, habitat, and economic performance
10 metrics in this Adaptive Management Plan.
- 11 **Preferred alternative** – The preferred alternative is the alternative that the agency
12 believes would best fulfill its statutory mission and responsibilities, giving
13 consideration to economic, environmental, technical, and other factors.
- 14 **PrOACT decision-making model** – An organized, structured decision-making
15 approach to identifying and evaluating creative options and making choices in complex
16 decision situations. PrOACT is a decision analysis approach currently employed by the
17 USACE in the development of the Missouri River Recovery Management Plan. It is a
18 technique used to provide analytical structure and rigor to values-based questions by
19 clarifying the consequences of alternate solutions, including the impacts on multiple
20 objectives. The unifying features of PrOACT analyses are that they involve: (1)
21 clarifying the Problem to be solved, (2) listing Objectives to be considered (usually with
22 associated performance metrics), (3) developing Alternative solutions to the problem as
23 stated, (4) estimating the Consequences of each of the alternatives on each of the
24 objectives in terms of the metrics (usually in the form of a consequence table of
25 alternatives versus objectives) and (5) explicitly evaluating the Trade-offs that are
26 revealed to exist between the alternatives, usually in a discursive setting.
- 27 **Problem** – A question or concern that is being addressed in the decision-making
28 process.
- 29 **Program** – The “Program” refers to those elements that are at the level of the overall
30 Missouri River Recovery Program such as the Work Plan and the Program
31 Management Plan.
- 32 **Project Implementation Report (PIR)** – Contains site-specific information,
33 alternative designs and project features, the anticipated benefits of the project, and

- 1 documentation for compliance with the National Environmental Policy Act (NEPA)
 - 2 disclosing the potential affects to the quality of the human environment from project
 - 3 implementation.
- 4 **Proxy metric** – Type of performance metric. Generally, a proxy metric is an indirect
 - 5 metric used to represent a natural metric like population number (e.g., number of boat
 - 6 ramp days). Proxy criteria are those that correlate well with objectives that are
 - 7 otherwise difficult to measure or estimate.
- 8 **Quantitative predictive models** – Numerical models used to predict biological and
 - 9 ecological responses as a function of management or restoration actions.
- 10 **Recovery plan** - A document drafted by the Service or other knowledgeable
 - 11 individual or group that serves as a guide for activities to be undertaken by Federal,
 - 12 state, or private entities in helping to recover and conserve endangered or threatened
 - 13 species.
- 14 **Risk** – An uncertainty coupled with an adverse consequence, ideally expressed as the
 - 15 product of the two components, with uncertainty represented as a probability.
- 16 **Section 7** - The section of the Endangered Species Act that requires all Federal
 - 17 agencies, in "consultation" with the Service, to ensure that their actions are not likely to
 - 18 jeopardize the continued existence of listed species or result in destruction or adverse
 - 19 modification of critical habitat.
- 20 **Selected alternative** – the alternative identified in the ROD that the agency intends
 - 21 to implement
- 22 **Spawning habitat** – Functional spawning habitat produces a successful hatch of
 - 23 embryos. For successful hatch to take place, hydraulics and substrate must be
 - 24 conducive first to attraction and aggregation of reproductive adults, followed by egg
 - 25 and milt release, fertilization, and deposition of eggs in a protected environment.
- 26 **Species objectives** – see fundamental and means objectives.
- 27 **Strategy table** – A visual tool for combining management actions into thoughtfully
 - 28 crafted alternatives.
- 29 **Structured Decision Making (SDM)** – Organized approach to identifying and
 - 30 evaluating creative options and making choices in complex decision situations. It is

- 1 used to inform difficult choices, and to make them more transparent and efficient.
 - 2 PrOACT is a specific application of SDM to collaborative problem solving.
- 3 **Sub-objectives** – The sub-objectives are aspects of the fundamental objective described in more detail that need to be addressed to achieve the fundamental objective. They are intended to provide direction in the short term, provide objectives meaningful for adaptive management, and focus efforts on the desired short-term outcomes while contributing to the fundamental objective.
- 8 **Success criteria** – A qualitative or (preferably) quantitative description of the conditions for which the parties agree that the objectives have been sufficiently met.
10 Usually expressed in terms of the performance metrics.
- 11 **Target** – Targets are a specific value or range of performance metric that define success. Targets can be quantitative values or overall trends (directional or trajectory).
- 13 **Trade-offs (also Trade-off analysis)** – A trade-off occurs when one alternative performs well on one metric but poorly on another relative to another alternative. Reasonable people may disagree about which is the best alternative because they value the two metrics differently; thus, value trade-offs involve making judgments about how much you would give up on one objective in order to achieve gains on another objective. By analyzing trade-offs, the PrOACT process tries to help find the alternative that (1) eliminates unnecessary trade-offs and (2) that people agree is the “best balance” of trade-offs possible.
- 21 **Trigger** – A form of decision criteria serving as a threshold or condition that, when met, initiates some action or decision.
- 23 **Uncertainty** – Circumstances in which information is deficient. Leaning while doing under the adaptive management process provides a framework for reducing program uncertainties over time.
- 27 **Upper Missouri River** – Mainstem of the Missouri River between Fort Peck Dam and the headwaters of Lake Sakakawea, and the Yellowstone River for an unspecified distance upstream of the confluence with the Missouri River.
- 31 **Variability** – A measure of how much a set of conditions differs from the mean or median state.
- 34 **Work Plan (also Strategic Plan)** – A rolling, 5-year plan outlining the management actions, monitoring, assessment, research, and engagement needs for the MRRP. It includes the details for the current FY and the FY+1 President’s Budget (P-bud) and planned activities for FY+2 through FY+4 for budgeting and other purposes.

- 1
- 2 **Working dominant hypotheses** – Set of plausible, biologically important
- 3 hypotheses, relevant to population dynamics of pallid sturgeon. Derived from
- 4 importance values in conceptual ecological model, scored by expert elicitation survey.
- 5
- 6
- 7 **Working management hypotheses** – Set of management hypotheses linking
- 8 management actions to working dominant hypotheses. Derived from pathways
- 9 identified in conceptual ecological models and matched to working dominant
- 10 hypotheses. Scored by expert elicitation survey.

1

3 **Executive Summary**

4
5
6
7

Note: An executive summary for Version 5 of the Draft AM Plan was prepared for the MRRIC (AMPV5 Summary, 2016). It targeted those not involved in day-to-day implementation of the program. Chapter 1 of this document serves as a summary of the AM Plan for agency personnel and others involved in its implementation. An executive summary will be prepared and included in the Final AM Plan.

8
9
10

1.1 Introduction

Note: This is a draft document and is subject to change. Further revision will occur in conjunction with the Draft MRRMP-EIS.

2

1.1. Overview, background and context

4 1.1.1 Overview

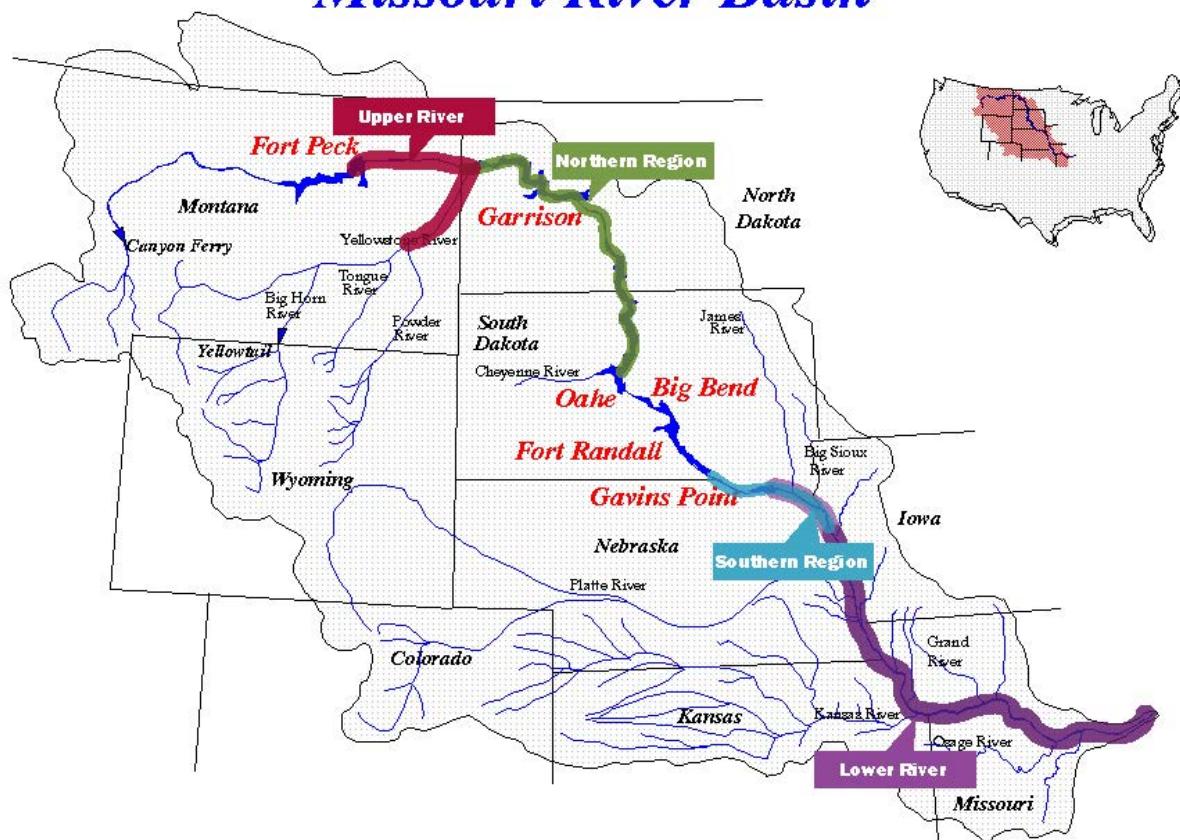

5 This introductory chapter serves as an executive summary, provides a guide to the
6 content of the Missouri River Recovery Program (MRRP or “the Program”) Science and
7 Adaptive Management Plan (AM Plan), outlines the content of subsequent chapters and
8 attachments, and summarizes the key points and concepts in each. Chapter 1 serves as
9 an executive summary and provides context to the individual chapters and attachments.
10 Parties intending to focus on only those sections of the document most relevant to their
11 interests should review this chapter to obtain that context. Chapter 2 describes the
12 organizational structure and decision processes for the governance of the AM Plan.
13 Subsequent chapters focus on the plan elements addressing the listed species (Chapters
14 3 and 4), stakeholder interests (Chapter 5), and describe plans for data management,
15 reporting, and communications (Chapter 6).

16 The final AM Plan that accompanies the Record of Decision (ROD) will be in a modular
17 format so that individual sections can be extracted and used to guide implementation of
18 the MRRP. Periodic updating of sections is expected, particularly in the first several
19 years of implementation as knowledge of what is needed for efficient and effective
20 operation is better understood. A lesson from the handful of existing AM programs for
21 large-scale ecosystem efforts is the need for early adjustments to the decision process,
22 decision criteria, monitoring programs, data management, and reporting and
23 communications practices. A process that demands self-evaluation, external review, and
24 periodic assessment of potential change is warranted, and agencies and stakeholders
25 must seek and embrace the changes needed to ensure the program’s success.

1 1.1.2 Missouri River Recovery Program (MRRP)

2 The Missouri River (

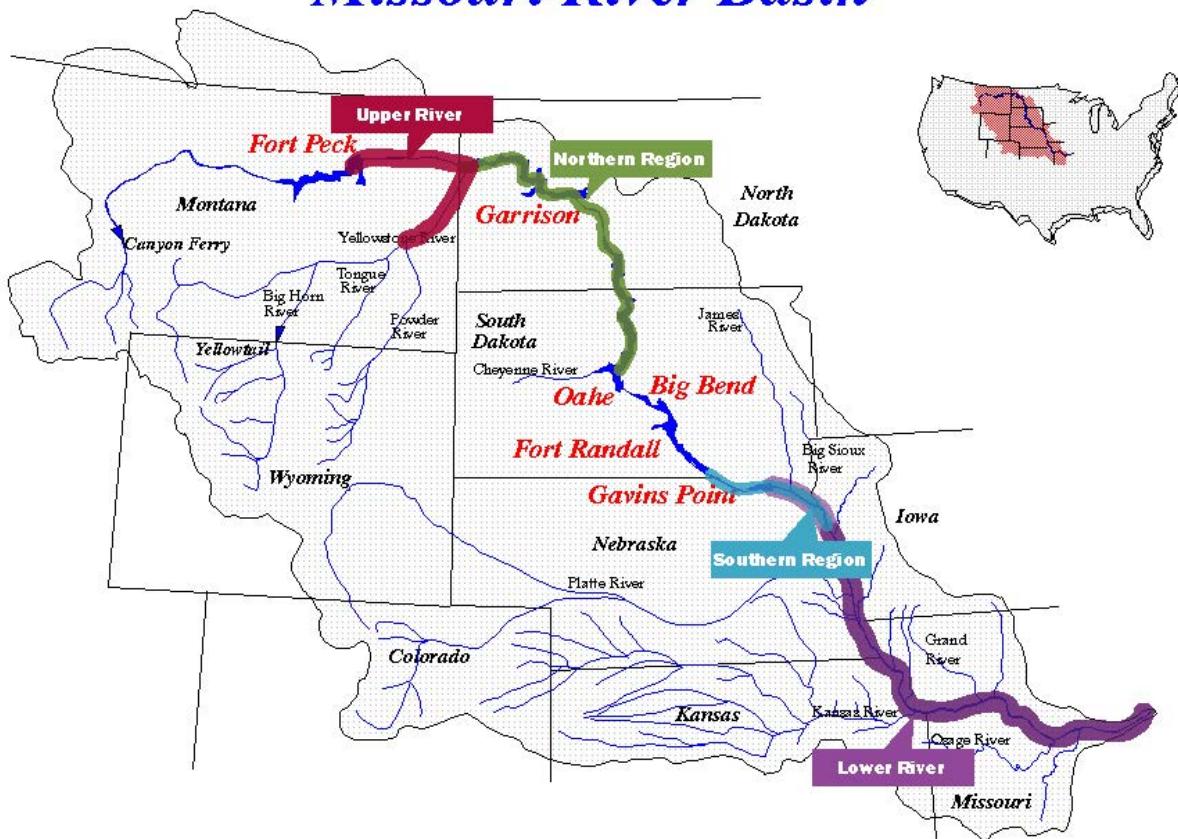

Missouri River Basin

3

4 Figure 1) was significantly altered in the nineteenth and twentieth centuries, including
5 the congressionally-authorized construction of six large reservoirs in Montana, North
6 Dakota, and South Dakota that constitute the Missouri River Mainstem Reservoir
7 System (System). The System is operated by the U.S. Army Corps of Engineers (USACE)
8 for multiple purposes, including flood control, hydropower, navigation, water supply,
9 irrigation, water quality, recreation, and fish and wildlife. Downstream of Sioux City, IA,
10 the river was channelized, revetted, and trained to provide a self-scouring navigation
11 channel. The USACE constructed, operates, and maintains this 1200-kilometer (km)
12 (735-mile) reach of the river under the Bank Stabilization and Navigation Project
13 (BSNP).

Missouri River Basin

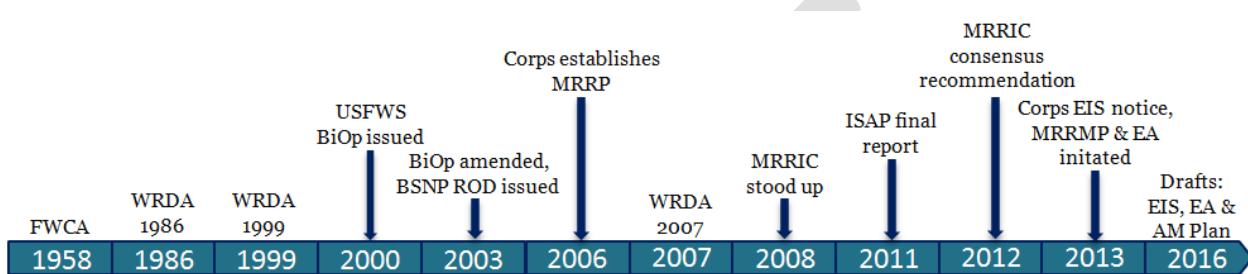

1

2 Figure 1. Missouri River Basin showing upper and lower river reaches for pallid sturgeon and northern
3 and southern regions for the piping plover. System reservoirs labeled in red.

4 Substantial changes in flow and sediment loads due to the System, coupled with the
5 physical alteration associated with the reservoirs and the BSNP, are manifest in changes
6 to the river's channel and floodplain habitats. The river has been reduced in length by
7 almost 320 km (200 miles), and as much as 12,000 km² (~4600 miles²) of river-
8 corridor habitats have been lost (National Research Council, 2002; USACE, 2004; Galat
9 et al. 2005). These changes to and losses of habitat have impacted native flora and fauna
10 using the system, including three federally-listed species: the pallid sturgeon
11 (*Scaphirhynchus albus*), interior least tern (*Sternula antillarum athalassos*), and the
12 piping plover (*Charadrius melanotos*) (U.S. Fish and Wildlife Service [USFWS] 2000).

13 The U.S. Fish and Wildlife Service (USFWS) issued a Biological Opinion (BiOp) in 2000
14 (see Figure 2 for an abbreviated event timeline) that found the USACE operation of the
15 System and the operation and maintenance of the BSNP would jeopardize the continued

1 existence of the pallid sturgeon, interior least tern, and piping plover (USFWS 2000¹).
 2 This 2000 BiOp, which applies to the portion of the Missouri River from Fort Peck, MT,
 3 to St. Louis, MO, and identified a Reasonable and Prudent Alternative (RPA) to
 4 jeopardy consisting of several actions to be taken by the USACE. New data were
 5 obtained regarding terns and plovers and RPA II (Flow Enhancement), and the USACE
 6 requested re-initiation of formal consultation and provided a biological assessment with
 7 new proposed actions to replace the spring and summer flows element.

8

9 Figure 2. Summary timeline of key events leading to this draft AM Plan,

10 In 2003, the USFWS provided a determination that the additional actions proposed by
 11 the USACE would avoid jeopardizing the continued existence of the two listed bird
 12 species, but continued to appreciably reduce the likelihood of both survival and recovery
 13 of the pallid sturgeon, thus jeopardizing its continued existence in the wild (USFWS
 14 2003; see Figure 2). The 2000 opinion and 2003 amendment (the USFWS 2003
 15 Amended Biological Opinion) are collectively referred to in this report as “the BiOp.”
 16 The BiOp also called for development of an Adaptive Management (AM) framework for
 17 resource management actions on the Missouri River, acknowledging critical
 18 uncertainties about how the Missouri River system functions and how species will
 19 respond to implemented management actions. For example, the 2003 Amended BiOp
 20 noted uncertainties about the effects of the timing, magnitude, and rate of change of
 21 releases from Gavins Point Dam on pallid sturgeon survival and that “*adaptive
 22 management is intended to address this kind of uncertainty.*” Given the uncertainties
 23 faced by the MRRP, AM provides a structured, organized, coherent, and transparent
 24 process that assesses and evaluates management actions in relation to program
 25 objectives so the program can make adjustments, as needed, to increase the likelihood
 26 of achieving desired outcomes.

27 The USACE established the MRRP in 2006 to implement the requirements of the BiOp
 28 and restore a portion of the Missouri River ecosystem and habitat for fish and wildlife,

¹ Please see these documents for a more nuanced and detailed discussion of the findings.

1 while maintaining the congressionally-authorized uses of the river. The MRRP consisted
2 of the following main elements:

- 3 • construction of Emergent Sandbar Habitat (ESH) for the birds and Shallow Water
4 Habitat (SWH) for pallid sturgeon and development and connection of low-lying
5 lands to benefit pallid sturgeon
6 • changes to releases from the reservoirs
7 • research, monitoring and evaluation, and AM of the management actions through an
8 Integrated Science Program (ISP)
9 • acquisition of lands through the BSNP Fish and Wildlife Mitigation project, of which
10 100,000 acres were directly related to the listed species
11 • public involvement.

12 Section 5018 of the 2007 Water Resources Development Act (WRDA) established the
13 Missouri River Recovery Implementation Committee (MRRIC), an assemblage of
14 stakeholders representing local, state, tribal, and Federal interests throughout the
15 Missouri River Basin, to make recommendation and provide guidance on MRRP
16 activities. The MRRIC was stood up in 2008 and is guided by its charter and operating
17 procedures and ground rules (see Attachments 1 and 2). The USACE and MRRIC are
18 assisted by an Independent Science Advisory Panel (ISAP or Panel) and an Independent
19 Social Economic Technical Review (ISETR) Panel, which afford technical oversight by
20 providing advice on specific topics identified by the agencies and/or MRRIC.

21 The first set of topics presented to the ISAP dealt with expected outcomes from
22 managed spring pulse releases from Gavins Point Dam; metrics, monitoring,
23 investigations, and management actions; and AM. In their 2011 final report, the ISAP
24 noted that “*there is not a comprehensive adaptive management plan for the recovery*
25 *program or for other recovery program components, all of which are interconnected*
26 *in their cumulative and interactive effects*” (Doyle et al. 2011). They suggested that such
27 a plan would contain essential components of any sound AM program, including
28 monitoring to collect the data necessary for evaluating management actions; a process
29 to evaluate past and guide future management actions using established performance
30 metrics and decision criteria; and a means to define success or failure. The ISAP also
31 noted that the development of an AM plan should be preceded by and based upon an
32 effects analysis (EA; see Section 1.1.4) that incorporates new knowledge that has accrued
33 since the 2003 Amended BiOp was issued (Doyle et al. 2011). An important component
34 of an EA as outlined by Murphy and Weiland (2011) is the development of an analytical
35 framework that supports quantification of the effects of alternative management plans
36 upon the demographics for the species of interest. This nominally requires population

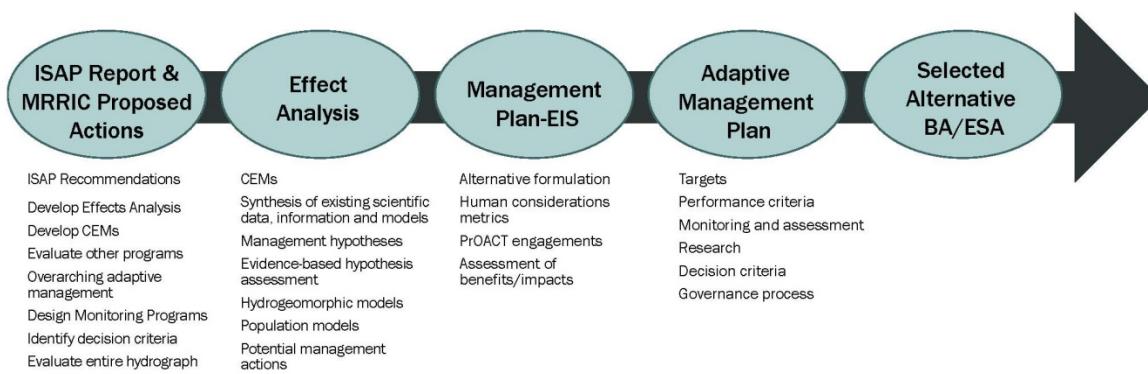

- 1 models for the species supported by models of the habitat and other factors affecting
- 2 those demographics (see Section 1.1.5).

- 3 The BiOp also called for development of an AM framework for resource management
- 4 actions on the Missouri River, acknowledging critical uncertainties about how the
- 5 Missouri River system functions and how species will respond to implemented
- 6 management actions. For example, the BiOp pointed out uncertainties about the effects
- 7 of the timing, magnitude, and rate of change of releases from Gavins Point Dam on
- 8 pallid sturgeon survival, noting that “*adaptive management is intended to address this*
- 9 *kind of uncertainty.*” Adaptive management provides a structured, organized, coherent,
- 10 and transparent process to assess, evaluate and adjust management actions in relation
- 11 to program objectives to increase the likelihood of achieving desired outcomes (see
- 12 Section 1.1.6).

- 13 In August 2012, the MRRIC made a consensus recommendation to the USACE, which
- 14 was based upon the ISAP’s report, and included seven proposed actions:

- 15 1. An EA should be developed that incorporates new knowledge that has accrued
- 16 since the USFWS 2003 Amended Biological Opinion. As part of this analysis the
- 17 following should be observed:
 - 18 a. The effects of the Missouri and Kansas River Operations on the three listed
 - 19 species should be reviewed and analyzed in the context of other stressors on
 - 20 the listed species.
 - 21 b. The quantitative effects of potential management actions on the three listed species
 - 22 should be documented to the extent possible.
 - 23 c. These potential management actions should be incorporated into the
 - 24 Conceptual Ecological Models (CEMs).
- 25 2. CEMs should be developed for each of the three listed species, and these models
- 26 should articulate the effects of stressors and mitigative actions (including but not
- 27 limited to flow management, habitat restoration actions, and artificial
- 28 propagation) on species performance.
- 29 3. Other managed flow programs and AM plans should be evaluated as guidance in
- 30 development of the CEMs and the AM strategy for the MRRP.
- 31 4. An overarching adaptive management strategy should be developed that
- 32 anticipates implementation of combined flow management actions and
- 33 mechanical habitat construction, and this strategy should be used to guide future
- 34 management actions, monitoring, research, and assessment activities within the
- 35 context of regulatory and legal constraints.

- 1 5. Monitoring programs along the Missouri River should be designed so as to
 2 determine if hypothesized outcomes are occurring and the extent to which they
 3 are attributable to specific management actions.
- 4 6. The agencies should identify decision criteria (trigger points) that will lead to
 5 continuing a management action or selecting a different management action. A
 6 formal process should be designed and implemented to regularly compare
 7 incoming monitoring results with the decision criteria.
- 8 7. Aspects of how the entire hydrograph influences the three listed species should be
 9 evaluated when assessing the range of potential management actions.
- 10 The USACE and USFWS agreed to implement these consensus recommendations
 11 collaboratively with MRRIC to arrive at a new management plan for the MRRP while (a)
 12 using a “structured effects analysis” as proposed by Murphy and Weiland (2011), (b)
 13 employing an AM framework, and (c) abiding by the requirements of the National
 14 Environmental Policy Act (NEPA). The resulting process, summarized schematically in
 15 Figure 3 and described in further detail below, led to the development of this AM plan.

- 16
- 17 Figure 3. Schematic of the process leading to development of the draft MRRMP-EIS and this draft AM plan. The
 18 AM Plan will be revised, as needed, prior to issuance of a record of decision (ROD).

- 19 The USACE published a notice in the Federal Register in August 2013 to prepare an
 20 Environmental Impact Statement (EIS) for the MRRP and initiated the Missouri River
 21 Recovery Management Plan (MRRMP), a multi-year planning effort to evaluate
 22 alternatives to avoid jeopardy to the listed species in light of the findings of the EA. The
 23 MRRMP-EIS provides a programmatic assessment of the MRRP including its impacts,
 24 cumulative effects, and alternatives to accomplish the purposes of the ESA (primarily
 25 Section 7), the 1958 Fish and Wildlife Coordination Act, section 601(a) of WRDA 1986,
 26 section 334 (a) and (b) of WRDA 1999, and section 3176 of WRDA 2007. The MRRP
 27 used the best available science from the EA to develop the integrated MRRMP-EIS and

1 identify a suite of actions that meets ESA responsibilities for the federally listed species
2 using Corps' authorities (see Section **Error! Reference source not found.**).

3 **1.1.3 Purpose and scope of the MRRP**

4 The purpose of the MRRP is to enable the USACE to operate the Missouri River System
5 (main stem reservoirs and BSNP), in accordance with the Missouri River Master Water
6 Control Manual, to meet its authorized purposes without jeopardizing the continued
7 existence of three species (piping plover, least tern, pallid sturgeon) listed under the
8 Endangered Species Act (ESA). The MRRP is the Corp's umbrella program for the
9 following:

- 10 • compliance with the USFWS 2003 Amended BiOp on the operation of the Missouri
11 River Main Stem Reservoir System (System), operation and maintenance of the
12 BSNP, and operation of the Kansas River Reservoir System
13 • acquisition and development of lands as authorized by Section 601(a) of WRDA 1986
14 and modified by Section 334(a) of WRDA 1999 (aka, the BSNP Fish and Wildlife
15 Mitigation Project)
16 • implementation of Sections 3176 and 5018 of WRDA 2007, extending recovery and
17 mitigation activities on the Missouri River to the upper basin states.

18 The MRRP is currently focused on implementing the requirements of the USFWS 2003
19 Amended Biological Opinion and is structured into several unique components
20 including the following:

- 21 • construction of Emergent Sandbar Habitat (ESH) for the birds and Shallow Water
22 Habitat (SWH) with development and connection of low-lying lands to benefit pallid
23 sturgeon
24 • propagation and hatchery support for the pallid sturgeon
25 • research, monitoring and evaluation, and adaptive management of management
26 actions through an Integrated Science Program (ISP)
27 • public involvement

28 The ESA requires consultation with USFWS in the event that an agency's action may
29 affect a listed species. The MRRMP-EIS is meant to serve as the basis for consultation
30 under the act and the development of the MRRMP-EIS, in coordination with USFWS, is
31 intended to result in a suite of actions that will avoid a jeopardy determination and be
32 implementable within the scope of the Corps' legal authority and jurisdiction. The
33 USFWS provided fundamental objectives, sub-objectives, targets, and metrics for each
34 of the three listed species pursuant to their responsibilities for administering the ESA,
35 and their jurisdiction and their special expertise as a cooperating agency on the

1 MRRMP-EIS. Achieving these objectives would meet the purpose and fulfill the need of
2 the plan.

3 The need to acquire and develop riparian and aquatic habitat on 166,750 acres of land,
4 as authorized by Section 334 of WRDA 1999 and recommended and described in the
5 2003 ROD (2003 ROD) for the BSNP Mitigation Project, is considered still relevant and
6 remains unchanged. Implementation of the mitigation project was expected to take
7 more than 30 years, but an annual rate of implementation was not specified given
8 budget uncertainties. Due to current and anticipated Assistant Secretary of the Army
9 (ASA) budget priorities, it is assumed that land acquisition over the implementation
10 timeframe for the MRRMP-EIS would continue to be focused on lands that can be used
11 to meet endangered species objectives while also contributing to BSNP mitigation. The
12 land acquisition and types of habitat development as described in the 2003 ROD are
13 still considered to be adequate and reasonable to mitigate the effects of the BSNP and
14 are recognized in all the alternatives described in the EIS. Habitat development would
15 be implemented on any acquired lands, which would be credited toward the BSNP
16 mitigation requirements.

17 **1.1.4 Effects Analysis (EA) and modeling framework for the MRRP**

18 The concept of an EA is rooted in the requirement within the ESA to use the best
19 available science when evaluating the effects that actions proposed by federal agencies
20 may have on listed species or designated critical habitat. Murphy and Weiland (2011)
21 advocated for a rigorous approach to an EA that begins with a definition of the proposed
22 action and the area affected. A conceptual model (or models) of the physical and
23 biological relationships relating the action(s) to species outcomes is prepared. Available
24 scientific information, including observations about the stressor and the range of
25 stressor conditions and information on population sizes and trends, is collected and
26 assessed for reliability. The next step includes assessment of the data, using
27 quantitative models to integrate existing information, and identifying and representing
28 uncertainties. The final step is to analyze the effect of proposed actions on the species to
29 determine costs and benefits and to identify alternatives.

30 The USACE adopted the ISAP's recommendations and MRRIC's corresponding
31 proposed actions regarding the EA, and contracted with an independent team to execute
32 the effort in August, 2013 (see Figure 2). The primary and relevant products of the EA
33 are summarized in a series of reports and embodied in a suite of models. Products of the
34 EA include the following:

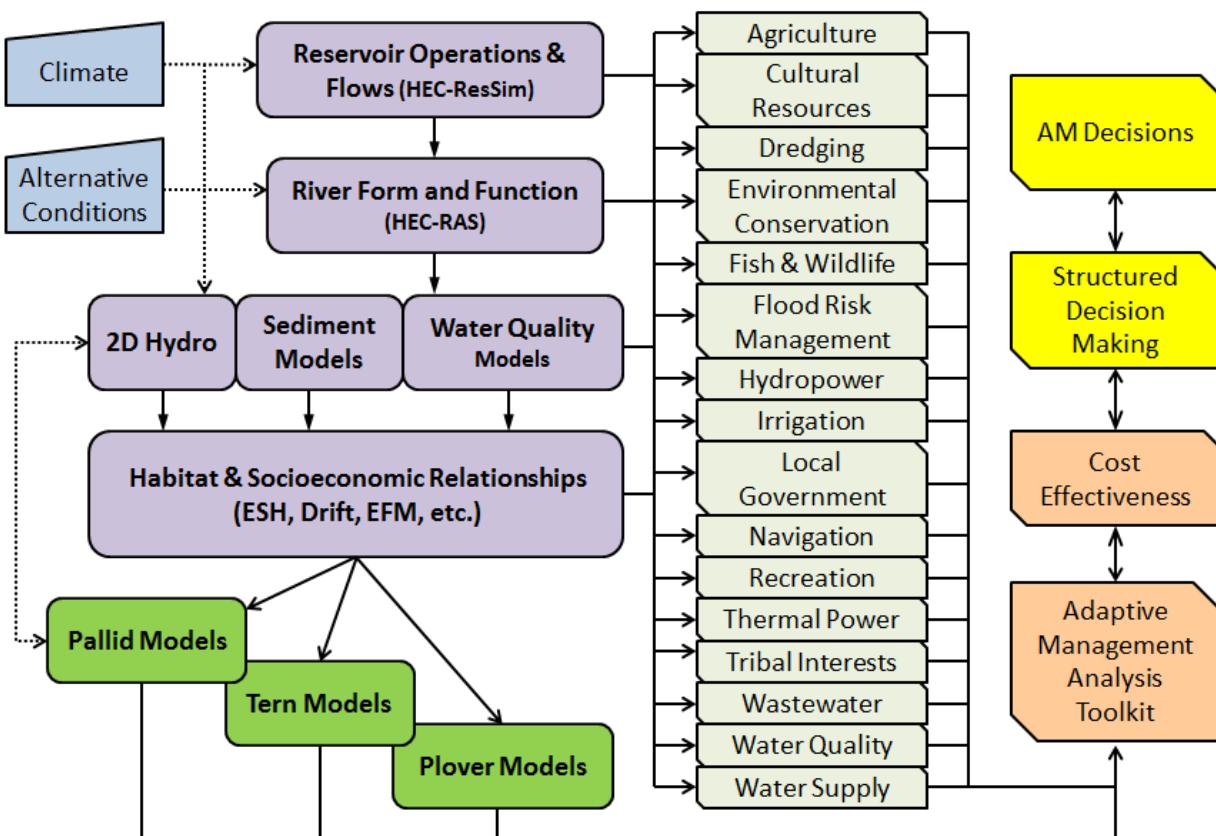

- 35 • Conceptual Ecological Models (CEMs) (Jacobson et al. 2015; Buenau et al. 2015)

- 1 • synthesis of existing models and scientific data/information reflecting the state of
- 2 science for the species and their habitats (Jacobson et al. 2015; Buenau et al. 2015;
- 3 Fischenich et al. 2015)
- 4 • hypotheses addressing critical uncertainties (Jacobson et al. 2015; Buenau et al.
- 5 2015)
- 6 • models of reservoir operations and hydraulic conditions (Fischenich et al. 2015),
- 7 habitat availability (Jacobson et al. 2015; Buenau et al. 2015; Fischenich et al. 2015),
- 8 and species demographics (Jacobson et al. 2015; Buenau et al. 2015)
- 9 • a variety of other papers, reports, methodologies, etc., supporting the development
- 10 of species targets, management actions and alternatives, and an AM plan.

11 A crucial component of the EA as outlined by Murphy and Weiland (2011) is the
12 development of an analytical framework that supports quantification of the effects of
13 alternatives upon the demographics for the species of interest. This nominally
14 requires population models for the species supported by models of the habitat and
15 other factors affecting those demographics.

16 A modeling framework advanced for the EA (Fischenich et al. 2014) and later applied to
17 the MRRMP-EIS is shown in Figure 4. The framework includes a suite of hydrologic,
18 hydraulic, and system operation models that feed critical habitat and population models
19 for each species as well as provides needed input to a wide array of algorithms and
20 models for assessing human considerations (HC) effects. The framework includes
21 models to address economic considerations and structured decision input.

22 The model types shown in Figure 4 should be regarded as categories of models or as
23 model codes; in all, more than 25 individual quantitative models have been developed to
24 support the combined needs of the EA and MRRMP-EIS. None of these models is stand-
25 alone; in some way, each model serves to support another modeling need or is reliant
26 upon other models for inputs. The specific models used in the framework and their roles
27 in supporting AM are discussed in later chapters of this plan and in the appendices.
28 Separate manuscripts for those models are also under development. Reports detailing
29 the HEC-RAS and ResSim models have been prepared and used for various model
30 reviews (references needed). All of the models have some source of uncertainty; the
31 magnitude and significance of that uncertainty varies, of course, and an important
32 aspect of the AM Plan is to work to improve the models and reduce uncertainty where
33 doing so may result in better decisions.

1

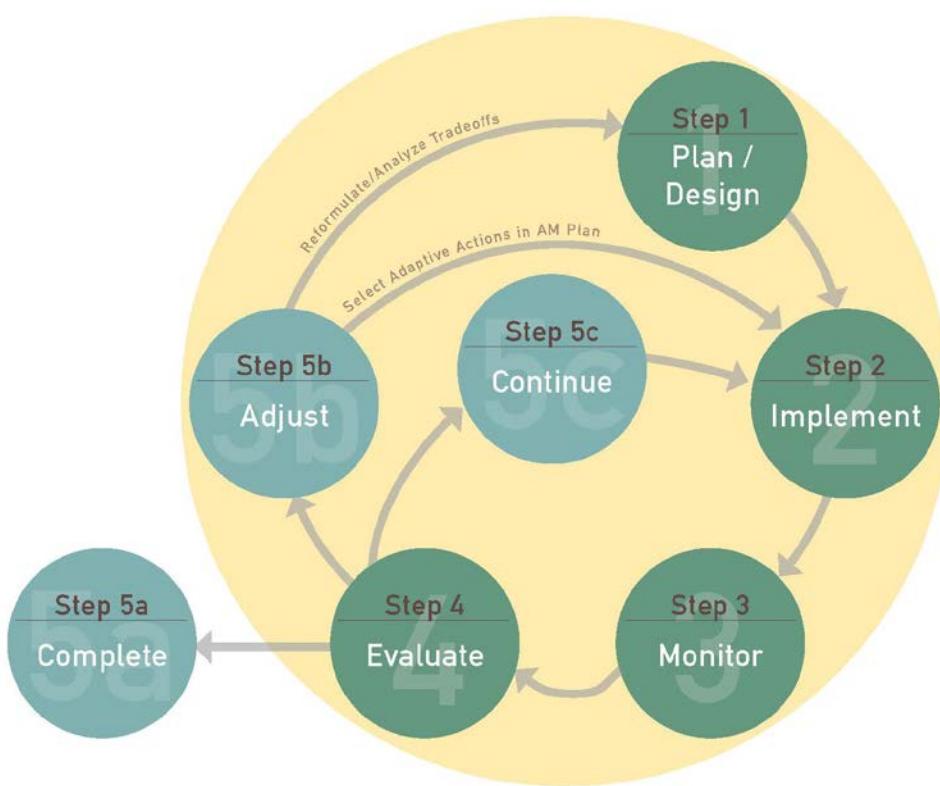

2 Figure 4. Model framework for the MRRP.

3 One logical extension of the EA models included projections of habitat availability and
 4 population response for various conditions to support alternative assessments and to
 5 develop species/habitat targets under the MRRMP-EIS. Another extension was the
 6 development of strategies to address the uncertainties and hypotheses identified as part
 7 of the EA, including the science, monitoring, and assessment activities identified in this
 8 AM plan. These products evolved through interactions among the EA team, the MRRMP
 9 Product Delivery Team (PDT), the ISAP, ISETR, the Independent Social Economic
 10 technical Review Panel (ISETR), and MRRIC and its committees.

11 The model framework is indispensable to the MRRP's implementation under AM. As
 12 described in detail in Chapters 3 through 5, models are applied in the plan and design
 13 phase of AM to determine where, when, and how the various management actions are
 14 used to meet objectives. The models are again applied in the evaluation phase to assess
 15 the implications of observed performance (population response due to monitored
 16 habitat changes) and determine management needs (using model projections of habitat
 17 and population for alternative management actions). The models are used to consolidate
 18 information, predict outcomes, quantify performance, and provide information needed
 19 by decision makers determine the best course of action under AM.

1 1.1.5 AM and decision-making concepts

2 At its most basic level, AM has been described as doing, learning, and adjusting. In
3 another simplified characterization (Figure 5), the “doing” part has been expanded to
4 include assessing (covered by the EA); planning, designing and implementing (Steps 1
5 and 2); the learning includes monitoring and evaluation (Steps 3 and 4); and in addition
6 to adjustments (Step 5b), learning can lead to decisions to continue with
7 implementation (Step 5c) or complete/terminate the action (Step 5a). Adjustment might
8 involve implementing actions that have been previously assessed in the planning
9 process (i.e., adaptive actions) that are triggered by decision criteria, or they may involve
10 more intensive reformulation through the planning process. Central to a progressive AM
11 program is the notion that learning is a primary objective, whether the issue is a
12 balanced portfolio of activities at the program level or the implementation of a specific
13 management action.

14

15 Figure 5. Simplified depiction of the AM process.

16 AM promotes collaboration, flexible decision-making through deliberately designing
17 and implementing management actions to test hypotheses and maximize learning about
18 critical uncertainties to better inform management decisions (Williams and Brown
19 2012). Collaborative AM is defined as “a systematic management paradigm that

1 assumes natural resource management policies and actions are not static, but are
2 adjusted based on the combination of new scientific and socioeconomic information.
3 Management is improved through learning from actions taken on the ecosystem being
4 affected. A collaborative AM approach incorporates and links credible science and
5 knowledge with the experience and values of stakeholders and managers for more
6 effective management decision-making" (Sims and Pratt-Miles 2011).

7 The MRRP AM Plan includes elements of both active and passive AM. Active AM
8 emphasizes knowledge as an intermediate objective toward the fundamental objectives,
9 and uses experiments or alternative management strategies to better understand system
10 behavior (i.e., it is typically hypothesis-driven). The knowledge gained is fed back into
11 the decision-making process, improving progress toward the fundamental objectives.
12 Passive AM is strictly driven by fundamental objectives, considering learning gained
13 through monitoring as secondary to the achievement of the fundamental objectives.

14 Establishing and implementing a formal monitoring and AM plan allows the USACE
15 and USFWS to determine if the suite of actions being taken are meeting objectives and,
16 if not, facilitates adjustments to those actions or the identification of new actions that
17 may be required. A collaborative governance process supported by clear objectives,
18 decision criteria, and a science program aimed at quantifying performance while
19 reducing critical uncertainties helps to ensure success.

20 **1.1.6 Relationship between MRRMP-EIS alternatives and actions in the AM Plan**

21 NEPA, in combination with the Council on Environmental Quality (CEQ) and USACE
22 regulations, require the USACE to prepare an EIS evaluating the impacts of a proposed
23 Federal action that will significantly affect the human environment. The EIS must
24 rigorously explore and objectively evaluate all reasonable alternatives that meet the
25 project's purpose and need. A thorough evaluation of the effects of alternatives on the
26 human environment is required so that an informed decision can be made in selecting
27 an alternative for implementation. Prior to alternative selection, the USFWS will be
28 consulted in order to ensure the selected alternative avoids jeopardy to the species.
29 Selection of an alternative will be formalized and documented in a ROD, which will be
30 issued by the USACE following completion of the MRRMP final EIS.

31 The high level of uncertainty regarding the type and extent of management actions
32 ultimately needed to meet the species objectives (especially for the pallid sturgeon)
33 requires a robust AM plan, which presents a challenge in identifying definitive
34 alternatives for NEPA evaluation. The approach used to address this situation was to
35 develop alternatives that would be initially implemented (over approximately a 15-year
36 timeframe) to begin the AM process. At the end of this timeframe, and potentially

1 sooner, another NEPA process would be undertaken to assess any changes, due to AM
2 or changes in the system, in the selected alternative that would be required to meet the
3 ESA needs. The alternatives in the draft EIS are combinations of management actions
4 derived from the EA findings and further screened based on effects to human
5 considerations and discussions with MRRIC. Speculation regarding management
6 actions that may be necessary to meet the species objectives beyond the 15-year
7 timeframe was not considered in the MRRMP-EIS given the degree of uncertainty.
8 However, effects of the alternatives were evaluated using were based on an 82-year
9 hydrologic period of record in order to provide an indication of effects under the
10 variable hydrologic conditions occurring in the Missouri River basin.

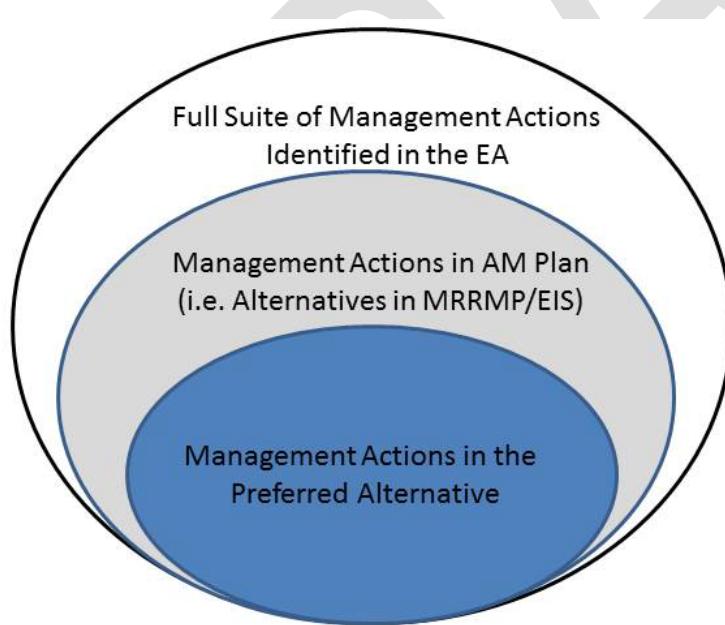

11 The Draft EIS (DEIS), released in December 2016 and accompanied by this AM Plan,
12 evaluated six alternatives (see Attachment 3 of Appendix A) and identifies a Preferred
13 Alternative. Research and related study activities needed to test hypotheses, including
14 those hypotheses for which specific management actions have not yet been identified
15 but may ultimately be required, are included in each alternative. These activities require
16 little or no ground disturbance or changes to reservoir release and do not cause effects
17 to the human environment. The research activities are thoroughly described the DEIS,
18 the draft AM Plan, and its appendices, and are key components MRRP since any of the
19 hypotheses from the EA (and potentially others not yet identified) may ultimately need
20 to be addressed in order to meet the species objectives.

21 The AM Plan describes the following:

- 22 1. The activities anticipated to be undertaken to assess the effectiveness of actions
23 implemented under the selected alternative,
- 24 2. The decision criteria used to determine if changes to management actions or to the
25 selected alternative are necessary,
- 26 3. Research and study activities to address hypotheses for which specific management
27 actions have not yet been identified, and
- 28 4. A governance process used to collaborate with stakeholders and make decisions.

29 The selected alternative, when one is identified in the ROD, will represent the agencies'
30 best estimate of the initial set of actions needed to achieve the species objectives. The
31 Final AM Plan will accompany the EIS and serve as the implementation plan for the
32 selected alternative and the MRRP into the foreseeable future. The AM Plan identifies
33 the process and criteria to implement the selected actions, assesses hypotheses, and
34 introduces new actions should they become necessary. The USACE will develop its
35 Biological Assessment (BA) on the basis of the MRRMP-EIS "package" including the
36 selected alternative and the AM Plan. Upon incorporation into a decision document the

- 1 Final AM Plan will serve as the implementation plan for the selected action and the
2 MRRP into the foreseeable future.
- 3 Establishing and implementing a formal monitoring and AM plan allows the USFWS to
4 determine if the suite of actions being taken are meeting species objectives that would
5 justify the removal or preclusion of a jeopardy determination, and if not, allows for
6 adjustments to those actions or identification of new actions within an AM framework.
- 7 Because the AM process may ultimately indicate the need for actions that address
8 hypotheses outside the scope of the selected alternative, a range of potential actions are
9 discussed within this AM Plan. Figure 6 is a schematic showing that the management
10 actions included in the Preferred Alternative are a subset of those in the AM Plan and
11 considered in the MRRMP-EIS, which in turn are a subset of the management actions
12 identified in the EA. The range of actions ultimately implemented could include those in
13 any of the three categories in Figure 6 as well as actions not yet evaluated. However, the
14 pathway to implementation, including required collaboration with MRRIC, additional
15 NEPA analysis, public engagement, and other requirements depends upon the category
16 in which the action lies (see Section 2.2.5). Only those actions that are part of the
17 selected alternative, as described in the ROD, could be implemented without further
18 requirements.

19

20 Figure 6. Schematic of management actions considered in the MRRMP-EIS, included in this AM Plan, and
21 included in the selected alternative.

1 Due to the nature of the interrelated Federal actions on the Missouri River, the
2 MRRMP-EIS employed a programmatic NEPA EIS, which enables the USACE to tier
3 future project proposals from the overarching programmatic EIS analysis, helping to
4 streamline future environmental reviews. CEQ regulations define tiering as covering
5 "general matters" in policy or program EISs with subsequent tiered or narrower
6 environmental analyses, while referencing the general discussion and focusing on the
7 project-specific impacts important to the decision maker. This approach is well suited to
8 the MRRP, as it integrates very well with AM. A programmatic EIS facilitates
9 responsiveness when monitoring indicates change to Federal actions because objectives
10 are not being met or new scientific understanding dictates alternative strategies, thus
11 strengthening the implementation of the plan. Implementation of specific projects or
12 management actions may require subsequent analysis that can be tiered from the EIS. If
13 the AM process provides new and significant information that requires actions not
14 included within the range of impacts and alternatives considered in this EIS, additional
15 NEPA analysis will be required. These considerations are described further in Chapter 4
16 of the DEIS and in Section 2.4.5 of the AM Plan.

17 **1.2 Adaptive Management (AM) governance**

18 Chapter 2 addresses the governance of the MRRP AM Plan, including a description of
19 what decisions need to be made, who would be involved in the decision-making process,
20 how decisions would be made, and when they would be required. Effective systems of
21 governance contribute to trust-building, knowledge generation, collaborative learning,
22 understanding of preferences, and conflict resolution. The proposed governance
23 structure and process for the MRRP is intended to achieve the program's aims and to
24 promote collaboration among the lead agencies, MRRIC, and others, while maintaining
25 the statutory decision-making responsibilities of each agency. While there are lessons to
26 be learned from other programs, there is no one-size-fits-all strategy; governance of the
27 MRRP needs to be designed for the MRRP, and be flexible enough to evolve as needed.

28 **1.2.1 AM decision needs**

29 Governance of the MRRP involves making decisions about topics ranging from highly
30 technical considerations, such as the selection of monitoring sites and sample sizes, to
31 policy- and value-laden issues, such as whether to adjust reservoir operations criteria.
32 Major policy decisions are made by the Corps' Division and District Commanders—
33 subject to their authorities and appropriations—with input from the USFWS, MRRIC,
34 and the public, when appropriate. Some decisions are a joint USACE and USFWS
35 function (e.g., changes to targets, decision criteria, or management actions). The MRRIC
36 works closely with the USACE and USFWS (agency) leaders, providing input on a full
37 range of decisions, and may provide consensus recommendations on any decision.

1 Section 2.2 describes the various decision needs, organized according to the AM cycle
2 (Figure 5) and at three levels of responsibility: oversight, management, and
3 implementation. Overlapping needs for the birds and fish are discussed in Section 2.2.2.
4 Program activities generally focus separately on the species, as there are few synergistic
5 or antagonistic effects from the proposed management actions due to the geographic
6 and temporal differences in species life-cycle needs and the limited scope of the actions
7 in the Preferred Alternative. However, decisions may be substantially affected by
8 unpredictable (in the long-term) processes and conditions, such as basin runoff and the
9 intermittent need to create ESH. Balancing species needs that differ over time requires
10 ongoing analysis, planning, risk management, and flexibility, and may require
11 acceptance that one or more objectives may not always be met.

12 Several processes external to the MRRP may impose important constraints on the
13 timing of decisions, WP development, engagement and implementation of the MRRP
14 (see Section 2.2.3). The most significant of these are the Corps' annual budget process
15 for Civil Works and the development of the Annual Operating Plan (AOP) for the
16 Missouri River Mainstem Reservoir System (System).

17 A recent study of judicial decisions on AM programs cited lack of decision criteria as one
18 of three key deficiencies that could lead to overturning of agency practice by the courts
19 (Fischman and Ruhl 2016). This AM Plan provides numerous decision criteria that
20 indicate actions based on performance of preceding actions, System status, species
21 populations, or results of hypotheses testing (see Section 2.2.4). New information or
22 understanding can inform adjustments to decision criteria, targets, MRRP objectives,
23 scope, or even MRRP governance structure and process itself (see Section 2.5).

24 Decision criteria are used in the MRRP to accomplish the following:

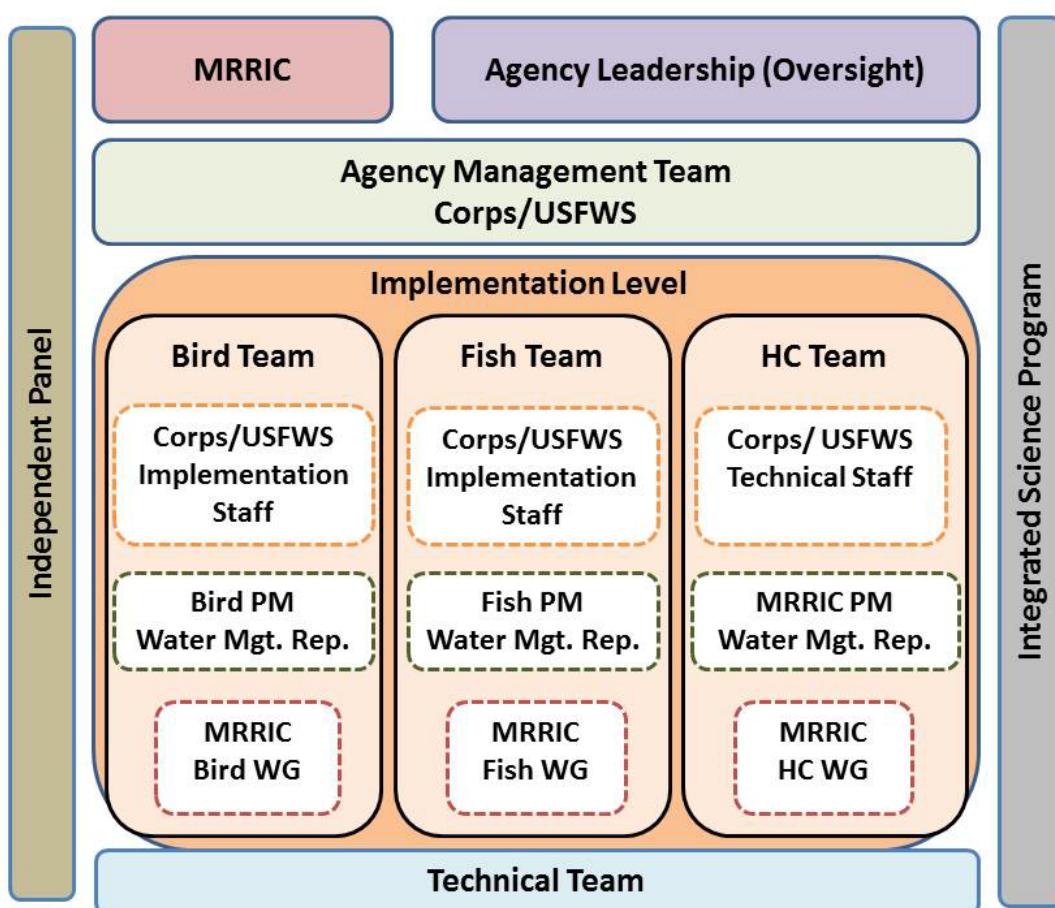

- 25 • define requirements for compliance purposes (e.g., ESA, NEPA, USACE policies)
- 26 • ensure that decisions incorporate best available science
- 27 • facilitate complex or time-sensitive decisions
- 28 • provide a clear(er) roadmap for participants (i.e., they define the decision space).

29 Section 2.2.5 discusses the NEPA EIS process and how it affects decisions related to the
30 implementation of management actions. The MRRMP-EIS employed a programmatic
31 NEPA EIS, which enables the USACE to tier future project proposals from the
32 overarching programmatic EIS analysis. Site-specific NEPA assessments may be
33 required in order to implement some elements of the Selected Alternative included in
34 the ROD, while others with adequate coverage in the EIS will be fully implementable.
35 Actions outside the ROD that may later be identified for implementation through the

- 1 AM process will require supplemental NEPA analysis and, if they involve flows, will
 2 require updating of the technical criteria in the Master Manual.

3 **1.2.2 Program composition, roles, and responsibilities**

4 As proposed in the AM Plan, governance starts with interagency teams working
 5 together, with the support of a Technical Team to interpret what has been learned to
 6 date and to apply that knowledge to future decisions. The Bird, Fish, and Human
 7 Considerations (HC) Teams, which include component MRRIC Work Groups (WGs)
 8 that provide expertise and perspective while also keeping the full MRRIC apprised of the
 9 teams' activities, propose management actions, monitoring, and assessment. The
 10 Management Team integrates the proposals from the Implementation Teams into a
 11 draft Work Plan (WP) that is reviewed by agency leadership and the MRRIC. Figure 7
 12 shows the elements that make up the basic governance structure for the MRRP.

13
 14 Figure 7. The proposed governance structure for AM of the MRRP.

15 A Technical Team patterned after the EA provides a non-decisional technical support
 16 function for the program (see Section 2.3.4). The Technical Team analyzes data,

- 1 conducts studies, and generates information used by the other teams for developing
2 decisions. The Technical Team includes subject matter expertise in ecology,
3 biostatistics, hydrodynamics, fluvial processes, decision analysis, river operations, and
4 socio-economics, and includes individuals with expertise and experience in assimilation
5 and analysis of information related to plovers, pallid sturgeon, and the
6 hydrogeomorphology of the Missouri River. Composition of the Technical Team may
7 include Federal and state agency personnel, university professors, and contractors
8 selected to address the underpinning science for the program. The Technical Team is
9 overseen by the AM Program Manager (AM PgM) through the Integrated Science
10 Program (ISP). Section 2.3.5 discusses the role of the ISP in overseeing much of the
11 contracting and implementation of the research, monitoring, and assessment for the
12 program. Attachment 14 of Appendix A provides details on the operation of the ISP.
- 13 Bird and Fish Teams comprised of agency implementation personnel and MRRIC WGs,
14 and overseen by the Bird and Fish PgMs, respectively, serve to filter the science and
15 performance information provided by the Technical Team, assess site characteristics
16 and alternative designs for management actions, consider model predictions of future
17 conditions, and make prioritized recommendations to the Management Team regarding
18 management actions for consideration as part of the WP. A description of the teams and
19 their decision responsibilities is provided in Section 2.3.3.1.
- 20 Decisions related to the WP process by the Management Team also receive input from
21 the HC Team, which is comprised of agency managers and technical experts together
22 with the MRRIC HC WG (see Section 2.3.3.2). The HC Team reviews and makes
23 recommendations for monitoring and assessment associated with the effects of MRRP
24 actions on HC interests. The Management Team, comprised of senior agency managers
25 (Section 2.3.2) uses input from the species and HC teams and formulates a draft WP for
26 consideration by agency leadership and the MRRIC. The species teams make some on-
27 the-ground implementation decisions, and the Management Team has a number of
28 responsibilities beyond development of the WP, mostly associated with budgeting,
29 resource allocation, product delivery, collaboration, and communications.
- 30 Each agency has the sole authority and jurisdiction to make decisions appointed it by
31 law. Senior leaders for the agencies provide oversight for the MRRP and are the ultimate
32 decision makers. The Corps Northwestern Division (NWD) Commander sets direction
33 for the Program, while the District Commanders are responsible for its execution. The
34 NWD Director of Programs provides the day-to-day oversight of the MRRP, frequently
35 represents the USACE in meetings with the MRRIC and/or USFWS, and may make
36 decisions related to the development of the WP, scheduling, resource allocation, and
37 other similar programmatic issues. The Region 6 Director is responsible for input and

1 decisions for the USFWS, while the Assistant Director for Ecological Services is the
2 USFWS counterpart to the NWD Director of Programs. The Oversight level of the MRRP
3 is described in Section 2.3.1.

4 In addition to the senior leaders and teams described above, Chapter 2 outlines the roles
5 and responsibilities of certain groups supporting leadership, including the ISP (Section
6 2.3.5), the Executive Steering Committee (ESC) (Section 2.3.6.1) and the Issue
7 Resolution Board (Section 2.3.6.9). Chapter 2 also provides descriptions of a number of
8 the key positions supporting the Program's oversight (see Section 2.3.6).

9 The (MRRIC) represents stakeholder interests for the MRRP. The MRRIC provides the
10 agencies with input on the Program's implementation, including recommendations for
11 changes to the implementation strategy from the use of AM. An overview of MRRIC role
12 and responsibilities is provided (Section 2.3.7), following a set of guiding principles, an
13 articulation of the MRRIC process and operating rules, and description of the levels of
14 engagement. Section 2.3.7.2 outlines the value and role of WGs to interface between the
15 MRRIC and the agencies on technical issues. By immersing in the science and
16 participating in related deliberations, WGs provide an effective means to build trust,
17 increase knowledge, and promote good decision-making that minimizes impacts to
18 stakeholder interests. The chapter describes the role of an Independent Science
19 Advisory Panel (Section 2.3.7.3) that provides review and guidance on science matters
20 (Section 2.3.7.3), and a Third Party Science Neutral (TPSN, Section 2.3.7.4), which
21 manages the Advisory Panel. The roles of basin states, other Federal agencies, and
22 Tribes outside the MRRIC collaborative process are addressed in Section 2.4.6.

23 **1.2.3 AM decision process**

24 The MRRP employs a rolling, adaptive, 5-year Work Plan. Because of the uncertainty
25 regarding some of the management actions required to meet species needs, future
26 implementation decisions for the MRRP depend upon the performance of earlier actions
27 and results of research addressing critical uncertainties (see Section 0). Knowledge
28 gained from project and system performance informs adjustments to the WP. The
29 process is constrained by several factors, most notably the timing of the Corps' budget
30 cycles, which dictate that updates to the WP include only minor adjustments to the
31 current fiscal year (FY) and the following FY (FY+1) budgets; center on development of
32 the FY+2 activities for budgeting purposes; and include anticipated needs for later years
33 (FY+3 and FY+4).

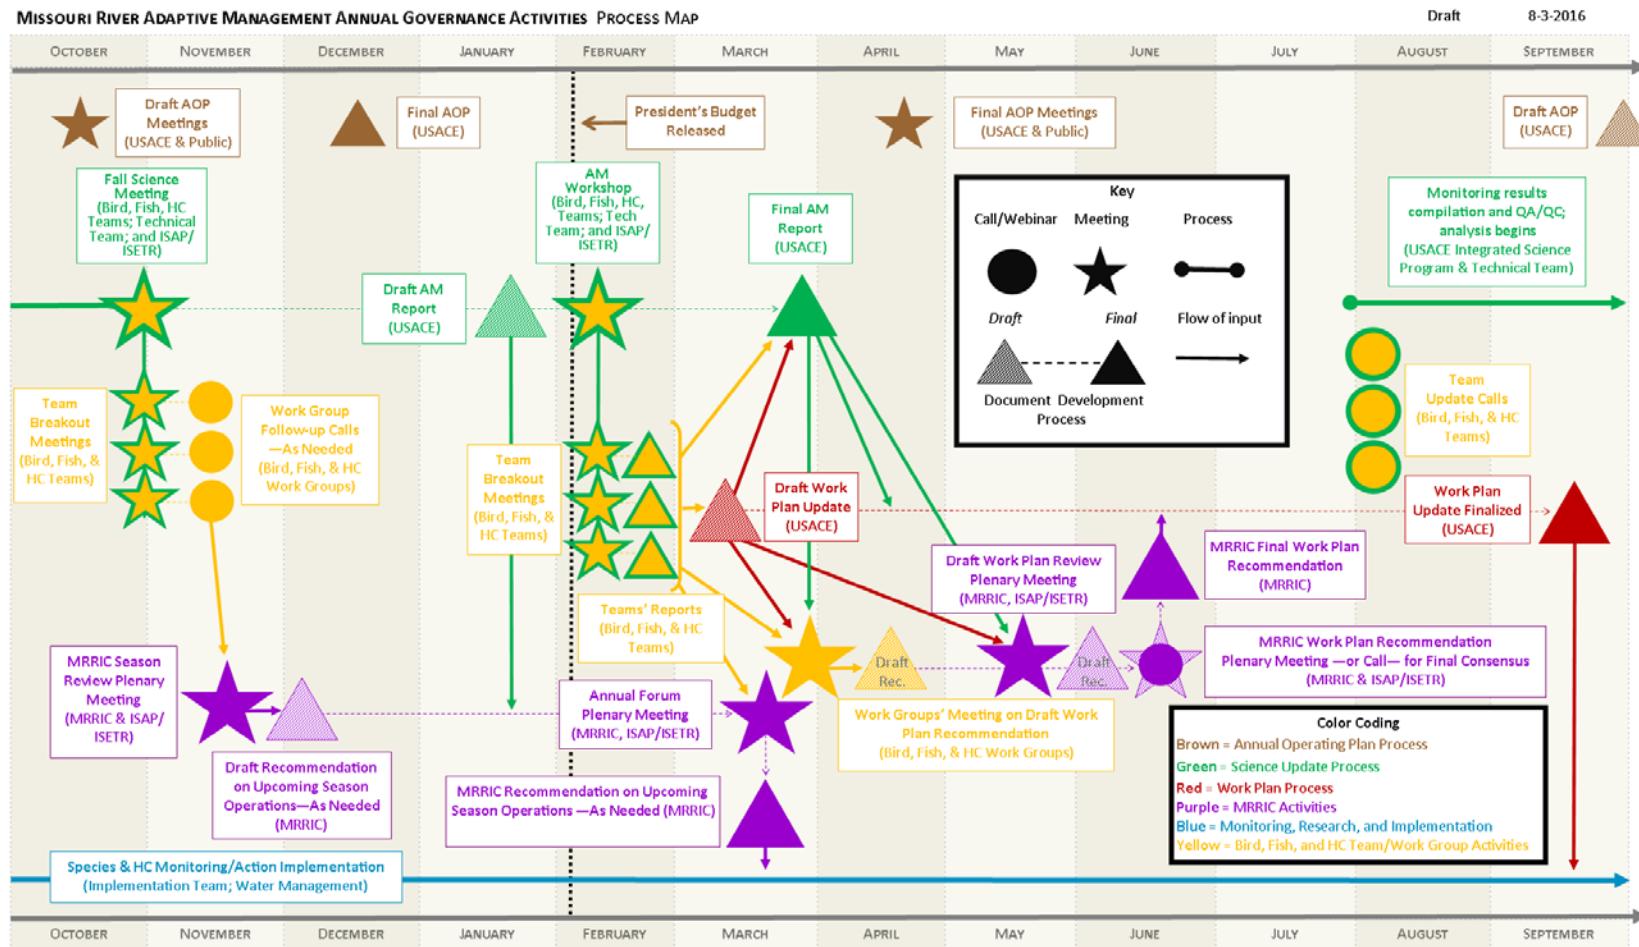

34 The processes and procedures by which the decisions are made are summarized in
35 Section 0. The annually recurring engagement process for the MRRP revolves around
36 science updates and the generation and sharing of information about program

1 performance, then using that information for the development/adjustment of the WP.
2 Figure 8 provides an overview of the process, which recurs each year for the Program.
3 The elements in the figure are described in Section 2.4.2.1.

4 In the beginning of each FY, the Technical Team meets with other entities at a Fall
5 Science Meeting to discuss the previous year's activities and to determine emerging
6 analytical needs and needs for modification of research plans. The Technical Team
7 would then assess actions implemented to date and the overall program performance;
8 summarize significant findings from research, monitoring, and assessment; update the
9 conceptual ecological models and hypotheses; make model projections of habitat and
10 species populations; assess Reservoir System status; and undertake other tasks or
11 studies needed to support decisions (Section 2.4.2).

12 Information generated by the Technical Team would be presented at an AM Workshop
13 held each February to provide an opportunity for USACE and USFWS decision-makers,
14 technical staff, contractors, and MRRIC to discuss the results of research and
15 monitoring for the previous year and plans for upcoming years (Section 2.4.3). The Bird
16 and Fish Teams would use information generated by the Technical Team to develop a
17 set of prioritized actions and program guidance for each species. The HC Team reviews
18 monitoring and assessment results related to the program's effects on HC metrics and
19 considers needed adjustments to the monitoring and assessment strategy. The Teams
20 (including the MRRIC WGs) would meet during and immediately following the AM
21 Workshop to prepare a report of recommendations and prioritized actions to submit to
22 the Management Team. The MRRIC WGs may prepare a separate joint WG Joint Report
23 to MRRIC and the agencies.

24 The Management Team would draft updates to the WP (Section 2.4.4) by integrating
25 recommendations and program guidance from the Bird, Fish, and HC Teams, and
26 applying a programmatic perspective that considers many factors, including the existing
27 WP makeup, guidance and direction provided by agency leadership, budget trends, the
28 status of the science, risk management, and effects on authorized purposes. A draft of
29 the revised WP would be prepared in early March and provided to the agencies and
30 MRRIC for review and comment. Proposed revisions would be discussed at MRRIC
31 meetings and by webinar, as needed. Additional analyses and adjustments could be
32 made during this process depending on the feedback received from agency leaders or
33 MRRIC. MRRIC may elect to provide a consensus recommendation at their June
34 meeting prior to the agencies' finalizing any adjustments to the plan.

1

2 Figure 8. Process map depicting the proposed governance activities to be undertaken annually by the USACE, the USFWS, and the Missouri River Recovery
 3 Implementation Committee (MRRIC) in the implementation of Adaptive Management for the Missouri River Recovery Program.

1 Section 2.4.5 presents the process for considering new management actions, outside
2 those in the ROD. A number of examples built around “decision workflow diagrams” are
3 detail the flow of information, products, and resulting decisions and indicate who is
4 involved in each (see Section 2.4.6). The timing of decisions is important, though
5 constrained by many factors, so the section uses timelines accompanying some of the
6 workflow diagrams as examples. It also addresses how the Annual Operating Plan (AOP)
7 for water management fits in, and does so for the Corps’ budgeting process as well.
8 Collectively, these processes along with the MRRIC engagement process, help to define
9 the overall operation of the AM Plan and indicates where issues might arise.

10 **1.2.4 Protocols and procedures**

11 A process section identifies a number of protocols and procedures that are necessary for
12 the administration and implementation of, and changes to the AM Plan (Section 2.5).
13 These include, for example, the procedures or protocols for changing the governance
14 structure, resurrecting reserve hypotheses, dispute resolution, and addressing cultural
15 resources uncovered during operations, as well as a host of other considerations. Details
16 of these procedures are presented as attachments to Appendix A (note: some are
17 placeholders – the details are yet to be developed or are in review/revision).

18 **1.2.5 Other key points and issues**

19 Governance for the MRRP is likely to evolve over time as lessons are learned about how
20 collaboration should occur and as program needs change. To that end, routine and
21 periodic reviews of the effectiveness of the program’s governance are needed, along with
22 a mechanism for change. As trust and understanding develop, decisions may be
23 delegated to lower levels and collaborative engagements will likely become less formal
24 and more effective. Section 2.5.6 lays out the processes for routine and periodic reviews
25 and the process for adapting the governance to fit learning and evolving program needs.

26 **1.3 AM for plovers and terns**

27 Managing for piping plovers and interior least terns largely involves ensuring sufficient
28 availability of ESH to support nesting and foraging for plovers, which the USFWS has
29 determined also meets habitat needs for terns, while accounting for any benefits to bird
30 populations from use of reservoir shorelines. Habitat and population models developed
31 for the plovers provide a powerful planning tool for managing the program, but
32 uncertainty about parameter estimates in the habitat models, coupled with observation
33 errors and uncertainty about dispersal, demographic rates, and their trends in the
34 population models provide significant opportunities for improvement in understanding
35 and management decisions.

1 The greatest near-term source of uncertainty is in estimating future flows, which drives
2 ESH availability. Managers will be required to make decisions about how much ESH to
3 create annually and how best to create it with consideration of the risk of falling short of
4 ESH targets. AM will likely revolve around the above issues, but opportunities exist for
5 meaningful improvements to the ESH construction methods, predator management,
6 and foraging habitat, among other things. Questions regarding the long-term availability
7 of sediments for building ESH in the riverine reaches will challenge team members to
8 find ever more efficient mechanisms to build and sustain needed habitat.

9 **1.3.1 Bird objectives, uncertainties, and targets**

10 The overall objective for piping plovers and least terns is to prevent USACE activities
11 from jeopardizing the continued existence of both bird populations in the Missouri
12 River. Objectives must be met for the Northern Region (Lake Sakakawea, Garrison
13 Reach, and Lake Oahe, see Figure 1) and the Southern Region (Fort Randall Reach,
14 Lewis and Clark Lake, and Gavins Point Reach, see Figure 1). Specific sub-objectives
15 pertain to long-term population persistence, population growth, increasing and
16 maintaining breeding success, and maintaining geographic distribution (see Section
17 3.1.1).

18 The EA built upon the Conceptual Ecological Models (CEMs) developed in 2013,
19 identifying critical uncertainties, management hypotheses, and a suite of associated
20 actions (see Section 3.1.2.4, Section 3.1.2.5, Table 1) that can be used to affect bird
21 populations. These overarching scientific uncertainties are the following:

- 22 • How much habitat is needed to maintain a resilient population of birds, and how
23 should it be distributed in space and time?
24 • How are the Missouri River populations of plovers and terns affected by migratory
25 and metapopulation dynamics?
26 • How will long-term changes in climate and channel morphology affect habitat and
27 species management?
28 • How can the bird AM program buffer against natural (especially hydrologic)
29 variability and uncertainty for long-term success?
30 • How can the bird AM program buffer against institutional and socioeconomic
31 variability and uncertainty for long-term success?

32
33 The management uncertainties, actions, and hypotheses are summarized in Table 1 and
34 are discussed in Section 3.1.2.5.

1 Table 1. Critical uncertainties related to bird management actions and associated management hypotheses.

Management Critical Uncertainties	Actions	Management hypotheses
Creating New Habitat What is the most effective and efficient way of creating habitat within the larger context of management and uses of the Missouri River?	Habitat-creating flows	Habitat-creating flows of sufficient magnitude and duration increase the area of nesting/brood rearing habitat and foraging habitat on the river by increasing deposition, assuming sediment is available, thereby increasing fledgling productivity.
a. Are there effective and implementable ways of using flow modification to provide and enhance habitat availability and quality? b. Can habitat be mechanically created in an effective and sustainable manner? c. What are the effects of habitat creation actions on HCs?	Mechanical habitat creation on river	Mechanical habitat creation of sandbars in river segments increases nesting/brood-rearing and foraging area, which increases survival of eggs to chicks and chicks to fledglings by reducing predation and increasing food availability. Mechanical habitat creation of sandbars in river segments increases nesting/brood-rearing and foraging area relative to the condition and availability of habitat at other breeding areas, thus increasing the number of adults through net immigration from other areas.
	Mechanical habitat creation on reservoir shorelines/islands or islands	Mechanical habitat creation of habitat on reservoir shorelines/islands increases nesting/brood-rearing and foraging area, which increases survival of eggs to chicks and chicks to fledglings by reducing predation and increasing food availability. Mechanical creation of habitat on reservoir shorelines or islands increases nesting/brood-rearing and foraging area relative to the condition and availability of habitat at other breeding areas, thus increasing the number of adults through net immigration from other areas.
	Mechanical creation of hydrologically-connected non-ESH habitat on river segments	Mechanical habitat creation of habitat other than ESH or in segments outside of the current ESH scope increases nesting/brood-rearing and foraging area, which increases survival of eggs to chicks and chicks to fledglings by reducing predation and increasing food availability. Mechanical habitat creation of habitat other than ESH or in segments outside of the current ESH scope increases nesting/brood-rearing and foraging area relative to the condition and availability of habitat at other breeding areas, thus increasing the number of adults through net immigration from other areas.

Maintaining Existing Habitat To what extent can maintaining existing habitat contribute to population objectives compared to creating new habitat? a. Does maintained habitat improve habitat metrics and support production equivalent to new habitat? b. Can flow be used to maintain habitat without increasing net erosion?	Modification or augmentation of existing sandbars	Modification or augmentation of existing sandbars increases nesting/brood-rearing and foraging area, which increases survival of eggs to chicks and chicks to fledglings by reducing predation. Modification or augmentation of sandbars increases nesting/brood-rearing and foraging area, which increases food availability and hence survival of chicks to fledglings. Modification or augmentation of existing sandbars increases nesting/brood-rearing and foraging area relative to the condition and availability of habitat at other breeding areas, thus increasing the number of adults through net immigration from other areas.
	Vegetation removal (spraying/mowing) on river/on reservoir	Vegetation removal increases nesting/brood-rearing and foraging area, which increases survival of eggs to chicks and chicks to fledglings by reducing predation (by increasing area and by removing cover for predators). Vegetation removal increases nesting/brood-rearing and foraging area, which increases survival of chicks to fledglings by increasing food availability. Vegetation removal increases nesting/brood-rearing and foraging area relative to habitat condition and availability of at other breeding areas, thus increasing the number of adults through net immigration from other areas.
	Habitat-conditioning flows	Habitat-conditioning flows are not of sufficient magnitude and duration to create new sandbars, but scour vegetation or deposit new sediment on existing bars, increasing the area of nesting/brood-rearing habitat, thereby increasing fledgling productivity.
Improving Availability of Existing Habitat To what extent can improving existing habitat availability through flows contribute to population objectives compared to creating new habitat?	Reservoir water level management	Declining reservoir water levels between years and/or steady or declining water levels during the nesting season increases the area of suitable nesting/brood rearing and plover foraging habitat on the reservoirs, thereby increasing fledgling productivity.
	Lowered nesting season flows	Lowered nesting season flows increase the area of suitable riverine nesting and brood rearing habitat and foraging habitat, thereby increasing fledgling productivity.
Population Protection To what extent can population protection actions positively contribute to the success of birds on the Missouri River?	Flow management to reduce take	Steady or declining reservoir levels and/or river flows during the nesting season increases survival from egg to chick and chick to fledgling by reducing the risk of nest inundation and chick stranding and by maintaining or increasing foraging habitat.
	Predator removal	Predator removal increases survival of eggs to chicks and chicks to fledglings.
	Nest caging	Nest caging protects plover nests from predators, increasing survival of eggs to chicks, though survival of adults may be negatively affected by cages.
	Human restrictions measures (signs, barriers, education)	Human restriction measures reduce activity on nesting and foraging habitat, increasing survival both by decreasing direct mortality and indirect effects on survival caused by stress.

- 1 A suite of models that relate reservoir operations, river flows, ESH availability, and bird
 2 populations is discussed in Section 3.1.2.3. The models provide a mechanism for
 3 projecting the probability distribution of future habitat area and bird population size.
 4 Using historical hydrological data, the models were applied to help establish targets for
 5 habitat based on a population viability analysis (see Section 3.1.1 for information on the
 6 models). Targets are presented in Section 3.2.3 for both ESH (see Section 3.2.2.1) and
 7 species metrics (see Section 3.2.2.2).
- 8 ESH targets for the Northern and Southern Regions are presented as a range of
 9 standardized ESH values (number of acres above a reference elevation) that should be
 10 met in 3 out of 4 years, and exceedance values for available ESH (number of acres at the
 11 highest stage during the nesting season) that must be met on a rolling 12-year average
 12 (see Table 2).
- 13 Table 2. Summary of standardized and available ESH acreage targets.

		Acres of ESH					
		Northern Region			Southern Region		
		2.5%ile	Median	97.5%ile	2.5%ile	Median	97.5%ile
Standardized ESH Acres		200	428	1996	264	782	3907
Available ESH Acres Exceeded for Percentage of Years	75%	140	210	470	280	370	700
	50%	380	630	1000	460	720	1580
	25%	770	1420	2010	780	1370	3285
	10%	1340	2230	3625	1130	2320	5275

- 14
- 15 Quantitative targets are provided for the piping plover only; the USFWS has determined
 16 that, by meeting the plover habitat objectives, the USACE will also fulfill least tern
 17 habitat needs for the Missouri River. Quantitative targets for the least tern may be
 18 added pending decisions regarding delisting and development of conservation plans.

19 **1.3.2 Implementing, monitoring, and evaluating bird actions**

- 20 Implementers of the MRRP will be faced with decisions about the above management
 21 actions with limited knowledge of future conditions that could significantly affect the
 22 amount of habitat and species populations, and without knowing precisely how the
 23 habitat and species will respond to those uncertain conditions. The role of AM in
 24 managing the birds is to improve decision-making in light of an uncertain future system
 25 state—an uncertainty that can never fully be resolved—and through improved
 26 understanding of how the system functions and responds to various management

1 actions. This, and the need to balance multiple and sometimes competing objectives for
2 species and HCs, supports the use of a “toolbox approach” wherein many management
3 actions and options are available to accommodate natural variability and socioeconomic
4 uncertainty (see Table 1). The initial set of management actions in the toolbox, and their
5 specifications, will be determined by the action agencies in collaboration with MRRIC
6 and specified in the ROD. As the AM Plan is implemented, knowledge gained about the
7 performance of implemented actions, including their effects on HC objectives, will be
8 used to make adjustments that increase their effectiveness. New knowledge may also
9 result in the addition or removal of management actions from the toolbox. Decisions
10 about such changes will be evidence-based and made in collaboration with MRRIC. HC
11 metrics (discussed in Chapter 5) are also identified in Chapter 3 where applicable to
12 management actions for the birds.

13 The following metrics will be used when testing the hypotheses in Table 1 and to support
14 management decisions (see Chapters 2, 3 and 5):

- 15 • Habitat metrics
 - 16 ○ Standardized ESH (acres)
 - 17 ○ Available ESH (acres)
 - 18 ○ Available shoreline (feet)
 - 19 ○ Inundation during the nesting season (feet)
- 20 • Species metrics
 - 21 ○ Population size
 - 22 ○ Population growth rate
 - 23 ○ Fledge ratio
- 24 • Metrics of management conditions
 - 25 ○ Standardized ESH (acres) and distribution
 - 26 ○ Vegetated habitat (acres)
 - 27 ○ Storage in reservoirs (million acre-feet) and planned releases (cubic feet per
28 second [cfs])
 - 29 ○ Tributary flows (cfs) and downstream stage (elevation)
 - 30 ○ Bird population density (adults/acre)
 - 31 ○ Budget (\$)

32 Some of these metrics have historically been collected under the Tern and Plover
33 Monitoring Program. Revisions to the monitoring program, which are under
34 development, will be described in Section 3.3 when completed.

35 Section 0 provides important details for each of the management actions under
36 consideration in the MRRMP EIS, including a description of each action,

1 implementation criteria, constraints to implementation, performance metrics, HC
2 metrics, uncertainties and needed research, criteria for adjusting an action, and the
3 decision and collaboration level. Details are provided for actions in the Preferred
4 Alternative and for those considered in other alternatives. Following the ROD, actions
5 included in the Selected Alternative will be available for full implementation, while
6 actions evaluated but not included may be considered for research or pilot projects.
7 Section 3.2.4.3 includes management actions not evaluated in the MRRMP EIS. These
8 actions have greater uncertainty about effectiveness but have been identified as
9 potential actions that should be evaluated through research, modeling, and pilot
10 projects. The evaluation process includes assessing ESH and population status,
11 management needs, hypotheses, and the updating and validation of predictive models.
12 Assessment of ESH status involves the use of the models, along with remotely sensed
13 imagery, to determine both standardized and available habitat during nesting and
14 fledging seasons. ESH acreage relative to median and 95% confidence intervals for
15 targets, along with trends, are evaluated for planning ESH creation needs (see Section
16 3.5.1; also see Table 2). Evaluating population requires assessment of population
17 resiliency under current management conditions through modeling and assessment of
18 observed fledge ratios and population growth and their trends (see Section 3.5.2).

19 Section 3.5.3 provides guidance for the overall evaluation of status and management
20 needs. Table 3 (reproduced from Table 35) categorizes ESH and species status and
21 communicates a recommended management pathway (e.g., continue, increase, or
22 decrease current rates of habitat creation). An evaluation of management conditions
23 including system storage, snowpack, ESH condition, vegetation and predator status,
24 budget, and the pallid sturgeon research and management needs provides
25 understanding of how the decision space may be constrained (see Section 3.5.4).

26 Chapter 3 also discusses the evaluations needed to address new information (Section
27 3.5.5), evaluate key relationships, hypotheses, and science questions (Section 3.5.6),
28 update and validate models (Section 3.5.7), deal with ancillary information (Section
29 3.5.10), and assess unexpected outcomes (Section 3.5.11).

30

31

32

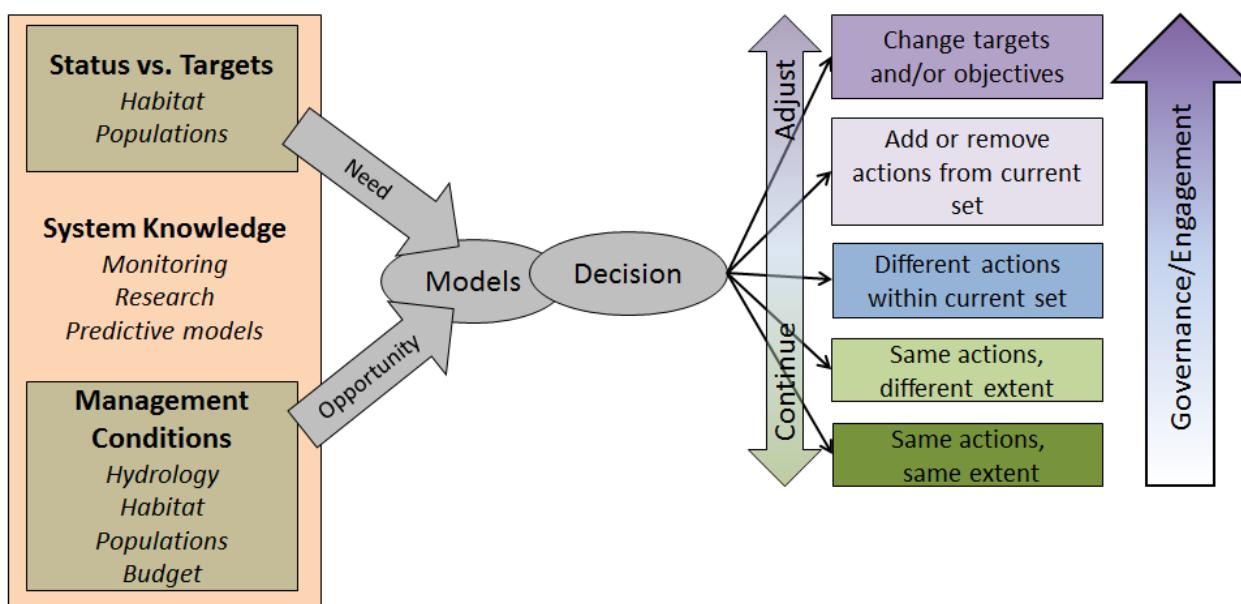

33

1 Table 3. Matrix for characterizing status and needs for ESH acreage and bird population. FR = Fledge Ratio
 2 (Number of fledglings observed / [number of breeding adults/2]); λ = lambda (population size in current year /
 3 population size in previous year).

Population Status	Emergent Sandbar Habitat Status			
	Acreage < Lower Bound	Lower Bound < Acreage < Median	Median < Acreage < Upper Bound	Upper Bound < Acreage
GROWING POPULATION FR and λ > target	On track to meet objectives Status: Small population OR density dependence less than expected Need: Continue pace of habitat creation	Meeting objectives Status: Moderate population, not habitat limited Need: Continue habitat creation at current or slower pace	Meeting objectives Status: Moderate to large population, not habitat limited Need: Maintain existing acreage and quality	Exceeding objectives Status: More birds and much more habitat than needed Need: Maintain habitat quality
STABLE POPULATION FR and λ ≈ target	Unlikely to meet objectives Status: Small to moderate population, becoming habitat limited Need: Increase rate of habitat creation	Meeting objectives Status: Moderate population, habitat may become limiting Need: Continue pace of habitat creation	Meeting objectives Status: Moderate to large population Need: Maintain existing acreage and quality	Exceeding objectives Status: More birds and more habitat than needed Need: Maintain habitat quality
DECLINING POPULATION FR and λ < target	Will not meet objectives Status: Small to large population, very habitat limited Need: Rapidly increase rate of habitat creation	Unlikely to meet objectives Status: Moderate to large population, habitat limited Need: Increase pace of habitat creation	Potential reversal Status: Large population returning towards equilibrium Need: Continue pace of habitat creation and maintain habitat	Reversal Status: Large population returning towards equilibrium OR density dependence much higher than expected Need: Maintain habitat quality, consider maintaining acreage

1 1.3.3 Decisions and planning contingencies

2 The decision process, decision criteria, necessary information and model projections, as
 3 well as guidelines and decision criteria for proceeding with specific management actions
 4 are presented in Section 3.6. This section also covers steps to be considered if objectives
 5 are not being met. Decisions can range along a continuum from implementing the same
 6 actions as in previous years to adjustments of varying degree including changing action
 7 specifications or criteria, adding new management actions, and changing targets or
 8 objectives. The decision process generally involves using new information from
 9 monitoring and research, modeling of habitat and population response, and
 10 management conditions (see **Error! Reference source not found.**). Contingency
 11 plans that provide a pre-specified roadmap to decisions are identified where feasible
 12 owing to their efficiency and effectiveness; however, the system is too complex and
 13 variable to pre-specify every contingency in a way that would be preferable to on-the-
 14 ground management decisions employing available information. Decisions are outlined
 15 for those actions evaluated in the MRRMP-EIS, not just those in the preferred
 16 alternative, to provide an overview of the full range of management possibilities prior to
 17 the ROD and should actions be added or expanded following the ROD and/or during the
 18 course of AM.

19

20 Figure 9. Factors affecting AM decisions for birds and the nature of those decisions.

21 The incremental costs and benefits of any management action(s) are considered during
 22 the decision cycle (as part of the WP development process). When more than one
 23 management action is possible, combinations and degrees of intensity for each action

- 1 should be considered to arrive at an optimum, or at least a preferred alternative. The
2 predictive models are necessary tools for these decision-support efforts. They also
3 provide a means of quantifying the risks associated with any decision. Model projections
4 of management actions are discussed in Section 3.6.2.1.
- 5 Decisions about how to create ESH (mechanical vs. flows) are discussed in Section
6 3.6.3.1. (That description includes flow modifications analyzed in the MRRMP EIS but not
7 included in the Preferred Alternative.) As previously identified, these decisions largely
8 turn on the amount of ESH needed as determined from the assessment stage, coupled
9 with an estimate of available budget (e.g., are funds available to mechanically construct
10 the full amount needed?), the potential for using flows (e.g., is system storage sufficient
11 and other conditions generally acceptable to the needed magnitude and duration of flow
12 releases?), and assessments of potential HC effects (positive and negative), synergistic
13 interactions, additional information learned, and pallid sturgeon management needs.
14 Close collaboration is required prior to implementation of any habitat-creating flows,
15 decisions to do so must be made at the Oversight level and other policy requirements
16 (e.g., NEPA evaluation, adjustments to Master Manual criteria) must be fulfilled.
- 17 Section 3.6.3.5 discusses decisions about whether to lower nesting season flows.
18 Flexibility to do so exists within the current technical criteria in the Master Manual
19 under some hydrologic conditions. Lowered summer flows can expose more nesting
20 habitat and delay creation of new ESH (see Section 3.6.3.5). Collaboration on lower
21 nesting season flows (within current Master Manual criteria) occurs through the AOP
22 process, as has been practiced in the past and/or communicated to stakeholders if made
23 in real time by the Missouri River Basin Water Management Division (MRBWMD). If
24 lowered summer flows as a deliberate, planned activity are anticipated, or if adjustments
25 to the Master Manual would be required to accommodate more substantive flow
26 management, a highhigh level of collaboration including public involvement would
27 occur, and those decisions would be made at the Oversight level.
- 28 Decisions about modifying existing habitat (Section 3.6.3.4) and predation management
29 (see Section 3.6.3.6) build upon existing knowledge and practice for these activities, as
30 well as proposed monitoring that should enhance understanding of key relationships for
31 these factors. The Management and Bird Teams generally make these decisions with
32 lower level collaboration and related actions would be included in the WP.
- 33 Decisions related to experiments and research activities are discussed in Section 3.5.6.
34 In addition to research targeting biological and management hypotheses, opportunities
35 for experimental implementation of management actions can be exercised to develop
36 more productive, efficient, and cost-effective means of achieving objectives. For

1 example, improvements in construction methods and resource (sand/sediment)
2 utilization may make mechanical construction more feasible. Similarly, innovative
3 methods for reducing erosion of ESH or managing vegetation and predators can extend
4 the life of existing ESH and help meet bird targets. Even improvements to monitoring
5 methods and more efficient analytical methods provide potentially significant
6 opportunities for programmatic cost savings and more effective decision-making.
7 Collaboration on research and experimental management actions will vary depending
8 on the nature of the activity, but would generally be consistent with any management
9 action included in the WP.

10 As models and scientific understanding are updated to reflect learning, the ESH targets
11 are recalculated to promote more efficient management. This occurs often enough to
12 allow learning to improve management outcomes, but not so frequently as to hinder
13 reasonable planning and assessment processes. Decisions to update habitat targets to
14 reflect learning or to revise targets or target criteria are addressed in Section 3.6.5.
15 Changes to the numerical targets to reflect new scientific understanding would be a
16 relatively routine process, but may warrant reviewed by the ISAP. Changes to target
17 criteria, or to objectives reflecting changes in regulations, values, or acceptable levels of
18 risk would involve technical review, but also require a higher level of collaboration and
19 Oversight-level approval.

20 **1.3.4 Other key points or issues**

21 While the understanding of the needs for the birds is significantly greater than for the
22 pallid sturgeon, costs for managing the birds can be high. Moreover, bird populations
23 (especially plovers) respond rapidly to the dynamic shifts in available habitat, and there
24 are many challenges to addressing their needs while minimizing impacts to HCs. These
25 factors contribute to the need for an active, progressive AM strategy as part of the
26 MRRP. Flow management for the birds remains a contentious issue, and should the
27 need for its use emerge, a progressive AM strategy with appropriate levels of
28 collaboration will be required to facilitate its implementation.

29 **1.4 AM for pallid sturgeon**

30 Despite considerable effort in previous years and an exhaustive attempt as part of the
31 EA, the identification of the specific factors causing recruitment failure for pallid
32 sturgeon and a clear nexus between management actions and population response
33 remains elusive for the lower river (downstream of Gavins Point Dam). While
34 fragmentation is clearly the primary factor in limiting or preventing recruitment on the
35 upper river (Ft. Peck Dam to the Lake Sakakawea Headwaters), other secondary factors
36 may also play a significant role and confound management decisions. Given the

1 lingering uncertainties regarding the scope and scale of the management actions
2 necessary for the USACE to avoid jeopardizing the continued existence of pallid
3 sturgeon, a strategy reliant upon a progressive AM program is the most effective way to
4 manage risks to the pallid sturgeon.

5 **1.4.1 Overview of Chapter 4**

6 Chapter 4 is organized around the AM cycle, beginning with the “Assess” step by
7 identifying the goals and objectives for pallid sturgeon (Section 4.1.1) and a summary of
8 the key findings of the EA (Section 4.1.2), including the hypotheses that emerged from
9 the effort, and the EA’s conclusions on those hypotheses. A pallid sturgeon framework
10 (developed jointly by the USACE and USFWS for the Lower Missouri River) is presented
11 in the “Plan/Design” step, and serves as a foundation for much of the AM strategy (see
12 Section 4.2.1). The framework describes four “levels” of action with progressively greater
13 influence on pallid sturgeon populations: Level 1 is research, Level 2 is focused field-
14 scale experiments, Level 3 is limited-scale implementation, and Level 4 is full-scale
15 implementation of management actions. Level 1 and 2 components of the framework are
16 detailed in the appendices (see Appendix C. Detailed Description of Level 1 and 2
17 Science Components for Pallid Sturgeon). Details for Level 3 and 4 actions are presented
18 in remaining sections of the chapter, and are generally summarized as they pertain to
19 the Upper Missouri River and Lower Missouri River.

20 **1.4.2 Pallid sturgeon objectives and key uncertainties**

21 The fundamental objective for pallid sturgeon, developed by the USFWS in 2013
22 (written com., September 12, 2013 [Draft Species Objectives, p. 1]), is to keep USACE
23 actions from jeopardizing the continued existence of pallid sturgeon in the Missouri
24 River. Sub-objectives are to increase recruitment to age 1, and to maintain or increase
25 numbers of pallid sturgeon as an interim measure until sufficient and sustained natural
26 recruitment occurs (see Section 4.1.1 for more details). Metrics have been defined for
27 these sub-objectives, but targets for these metrics are still to be determined.

28 The EA evaluated available reports and models, as well as other scientific literature, to
29 provide an integrated assessment of the current state of the science and understanding
30 of the potential benefits of management actions for pallid sturgeon in the Missouri
31 River, and associated uncertainties in that assessment (see Section 4.1.2). The EA also
32 introduces development of a collaborative population dynamics model developed to
33 support the MRRP AM Plan (Section 4.1.2.3).

34 Uncertainties for pallid sturgeon identified in the EA have been expressed as Big
35 Questions related to potential management actions with underlying hypotheses. There

1 are six Big Questions each for the Upper River and the Lower River, and each Big
2 Question includes underlying hypotheses. These are summarized in Table 4 and in Table
3 5 for the Upper Missouri River and Lower Missouri River, respectively. New information
4 (see Sections 2.5.4 and 6.2.5) may arise which leads to a re-examination of hypotheses
5 from the reserve list of EA hypotheses, the addition of new hypotheses, the revision of
6 existing hypotheses, or the removal of some of the existing hypotheses in the event of
7 strong evidence against them.

8 **Table 4. Big Questions and hypotheses for Level 1 and 2 components for the Upper Missouri River. Hypotheses**
9 **are from Table 1 in Jacobson et al. (2016a).**

Big Question 1 – Spawning Cues: Can spring pulsed flows from Fort Peck synchronize reproductive fish, increase chances of reproduction and recruitment?

Associated Hypothesis:

H2. Attractant flow releases at Fort Peck will result in increased reproductive success through increased aggregation and spawning success of adults.

Big Question 2 – Food and Forage: Can naturalization of the flow regime from Fort Peck contribute to increased food production, foraging habitat, and survival of age-0 sturgeon?

Associated Hypothesis:

H1. Naturalized flow releases at Fort Peck will result in increased productivity through increased hydrologic connections with low-lying land and floodplains in the spring, and decreased velocities and bioenergetic demands on exogenously feeding larvae and juveniles during low flows in summer and fall.

Big Question 3 – Temperature Control: Can water-temperature manipulations at Fort Peck contribute significantly to increased chance of reproduction and recruitment?

Associated Hypotheses:

H4. Warmer flow releases at Fort Peck Dam will increase system productivity and food resource availability, thereby increasing growth and condition of exogenously feeding larvae and juveniles.

H5. Warmer flow releases from Fort Peck Dam will increase growth rates, shorten drift distance, and decrease mortality by decreasing free embryos transported into headwaters of Lake Sakakawea.

Big Question 4 – Sediment Augmentation: Can sediment bypass at Fort Peck contribute significantly to increased chance of reproduction and recruitment?

Associated Hypothesis:

H6. Installing sediment bypass at Fort Peck will increase and naturalize turbidity levels, resulting in decreased predation on embryos, free embryos, and exogenously feeding larvae.

Big Question 5 – Drift Dynamics: Can combinations of flow manipulation from Fort Peck, drawdown of Lake Sakakawea, and fish passage at Intake Dam on the Yellowstone River increase probability of successful dispersal of free embryos and retention of exogenously feeding larvae?

Associated Hypotheses:

H3. Reduction of mainstem Missouri flows from Fort Peck Dam during free-embryo dispersal will decrease mainstem velocities and drift distance thereby decreasing mortality by decreasing numbers of free embryos transported into headwaters of Lake Sakakawea.

H7. Fish passage at Intake Diversion Dam on the Yellowstone River will allow access to additional functional spawning sites, increasing spawning success and effective drift distance, and decreasing downstream mortality of free embryos and exogenously feeding larvae.

H10. Drawdown of Lake Sakakawea will increase effective drift distance, decreasing downstream mortality of free embryos and exogenously feeding larvae.

Big Question 6 – Population Augmentation. Can population augmentation (stocking) processes be enhanced to increase survival and genetic fitness of stocked fish?

Associated Hypotheses:

H8. Stocking at optimal size classes and in optimal numbers will increase growth rates and survival of exogenously feeding larvae and juveniles.

H9. Stocking with appropriate parentage and genetic diversity will result in increased survival of embryos, free embryos, exogenously feeding larvae, and juveniles.

1
2

3 Table 5. Big Questions and hypotheses for Level 1 and 2 components for the Lower Missouri River.

Big Question 1 – Spawning Cues: Can spring pulsed flows synchronize reproductive fish, increase chances of reproduction and recruitment?

Associated Hypothesis:

H11. Naturalization of the flow regime at Gavins Point Dam will improve flow cues in spring for aggregation and spawning of reproductive adults, increasing reproductive success.

Big Question 2 – Temperature Control: Can water-temperature manipulations at Fort Randall and/or Gavins Point contribute significantly to increased chance of reproduction and recruitment?

Associated Hypothesis:

H15. Operation of a temperature management system at Fort Randall Dam and/or Gavins Point Dam will increase water temperature downstream of Gavins Point, providing improved spawning cues for reproductive adults.

Big Question 3 – Food and Forage: Can naturalization of the flow regime or channel reconfiguration (alone or in combination) contribute to increased food production, foraging habitat, and survival of age-0 sturgeon?

Associated Hypotheses:

H12. Naturalization of the flow regime at Gavins Point Dam will improve connectivity with channel-margin habitats and low-lying floodplain lands, increase primary and secondary production, and increase growth, condition, and survival of exogenously feeding larvae and juveniles.

H13. Naturalization of the flow regime at Gavins Point Dam will decrease velocities and bioenergetic demands, resulting in increased growth, condition, and survival for exogenously feeding larvae and juveniles.

H17. Re-engineering of channel morphology in selected reaches will increase channel complexity and bioenergetic conditions to increase prey density (invertebrates and native prey fish) for exogenously feeding larvae and juveniles.

H18. Re-engineering of channel morphology will increase channel complexity and minimize bioenergetic requirements for resting and foraging of exogenously feeding larvae and juveniles.

Big Question 4 – Drift Dynamics: Can naturalization of the flow regime or channel reconfiguration (alone or in combination) contribute to decreased direct mortality and increased interception of free embryos into supporting habitats?

Associated Hypotheses:

H14. Alteration of the flow regime at Gavins Point can be optimized to decrease mainstem velocities, decrease effective drift distance, and minimize mortality of free embryos.

H19. Re-engineering of channel morphology in selected reaches will increase channel complexity and serve specifically to intercept and retain drifting free embryos in areas with sufficient prey for first feeding and for growth through juvenile stages.

Big Question 5: Spawning Habitat. Can channel reconfiguration and spawning substrate construction increase probability of survival of eggs through fertilization, incubation, and hatch?

Associated Hypothesis:

H16. Re-engineering of channel morphology in selected reaches will create optimal spawning conditions -- substrate, hydraulics, and geometry -- to increase probability of successful spawning, fertilization, embryo incubation, and free-embryo retention.

Big Question 6: Population Augmentation. Can population augmentation (stocking) processes be enhanced to increase survival and genetic fitness of stocked fish?

Associated Hypotheses:

H20. Stocking at optimal size classes and in optimal numbers will increase growth rates and survival of exogenously feeding larvae and juveniles.

H21. Stocking with appropriate parentage and genetic diversity will result in increased survival of embryos, free embryos, exogenously feeding larvae, and juveniles.

1

2 **1.4.3 Pallid sturgeon framework**

3 The USACE and USFWS collaborated to develop a framework for adaptively managing
4 pallid sturgeon on the lower river. Referred to as “the Framework”, it consists of four
5 levels of activity as described in Table 6. As information is developed through Level 1
6 and 2 research and experiments (see Appendix C) or through monitoring of
7 effectiveness of management actions, decision criteria described in the Framework and
8 in Chapter 4 will be used to determine when and what actions should follow. Decisions
9 might include (a) accepting that the scientific information supports the hypothesized
10 action and moving to the next issue or level of implementation; (b) determining that the
11 scientific information does not support the hypothesized action and refining or rejecting
12 the hypothesis; or (c) deciding to implement at Level 3 because an agreed-upon time
13 limit has been reached and results remain equivocal (studies at Levels 1 and 2 might
14 continue concurrently). At any time during implementation, it may become apparent
15 that: 1) a particular action is not needed, 2) a proposed action requires modification to
16 be effective, or 3) some new action not previously evaluated is required.

- 1 Level 1 and 2 studies are directly tied to those uncertainties and management
 2 hypotheses highlighted in the EA that, if resolved, could significantly affect the
 3 implementation of management actions. Studies at Levels 1 and 2 may continue
 4 concurrently with Level 3 efforts, but are generally intended to inform actions at Level 3.
 5 Although Level 2 studies have learning as a primary objective, they can also provide
 6 measurable benefits to pallid sturgeon populations and, in such cases, are counted
 7 toward targets in the same manner as Level 3 actions. Criteria for accepting or rejecting
 8 specific hypotheses, for assessing the results of scaled experiments, and for moving from
 9 Level 1 to Level 2 or Level 2 to Level 3 actions, are described in section 4.2.4.
- 10 **Table 6. Pallid sturgeon framework for the lower Missouri River.**

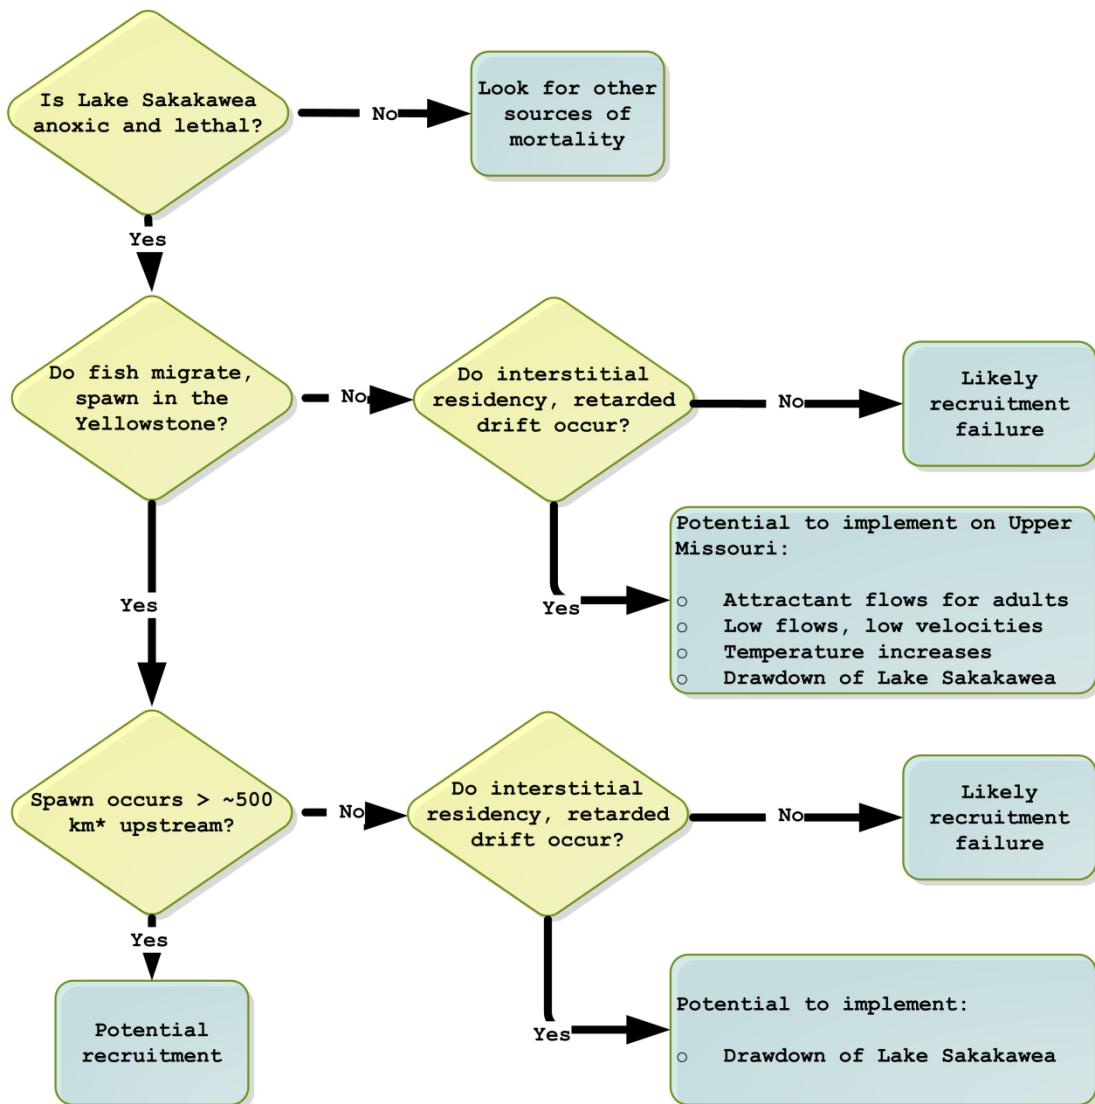

Level 1: Research	Population Level Biological Response IS NOT Expected	Studies without changes to the system (laboratory studies or field studies under ambient conditions)
Level 2: In-river Testing		Implementation of actions at a level sufficient to expect a measurable biological, behavioral, or physiological response in pallid sturgeon, surrogate species, or related habitat response.
Level 3: Scaled Implementation	Population Level Biological Response IS Expected	In terms of reproduction, numbers, or distribution, initial implementation should occur at a level sufficient to expect a meaningful population response progressing to implementation at levels that result in improvements in the population. The range of actions within this level is not expected to achieve full success (i.e., Level 4).
Level 4: Ultimate Required Scale of Implementation	IS Expected	Implementation to the ultimate level required to remove as a limiting factor.

- 11
 12 The Framework is expected to accelerate the identification of recruitment bottlenecks,
 13 resulting in a more strategic and focused implementation of appropriate management
 14 actions. This approach has the added benefit of minimizing impacts to stakeholders and
 15 avoiding unnecessary implementation costs. Though developed for use on the Lower
 16 River, the terminology from the Framework is used in describing needs for the Upper
 17 River as well.

18 **1.4.4 Pallid sturgeon in the Upper Missouri River**

- 19 For the Upper Missouri and Yellowstone Rivers, fragmentation that limits the available
 20 drift/dispersal distance and hypothesized inhospitable headwaters of Lake Sakakawea
 21 due to anoxic sediments pose a distinct constraint on recruitment. Big Questions for the
 22 Upper Missouri River relate to management actions that are hypothesized to increase
 23 natural recruitment (see Table 4). From this broader set of Big Questions and
 24 hypotheses, policy determinations have been made to focus implementation on actions

- 1 that are either currently being implemented and re-evaluated (e.g., population
2 augmentation, under review by the Pallid Sturgeon Recovery Team) or are proposed
3 (e.g., fish passage at Intake Diversion Dam).
- 4 Implementation of fish passage at Intake Dam has been identified by the USFWS as
5 sufficient for avoidance of jeopardy, provided the passage is effective (the immediate
6 objective) and results in recruitment (the broader objective). The fundamental scientific
7 uncertainty related to Intake passage is whether reproductive adults will find passage
8 around or over Intake Dam and migrate a sufficient distance upstream for spawning
9 (500 kilometers [km] is the hypothesized distance needed for drift of free embryos).
10 Resolution of this uncertainty will have a profound effect on the ability to predict
11 whether recruitment is possible in the Upper River.
- 12 Key metrics for the fish passage structure itself would be, monitored by the Bureau of
13 Reclamation and, are described in the Monitoring and Adaptive Management Plan for
14 the Lower Yellowstone Passage Project (Reclamation 2016). Monitoring under the AM
15 Plan for the MRRP is focused on using telemetry tags on adult pallid sturgeon to test the
16 response of adult spawning in the upper Yellowstone River to improved passage at
17 Intake, assessing drift of free embryos downstream past Intake Dam, and assessing the
18 longer term population response to passage improvements at Intake Dam.
- 19 As part of the MRRP, the USACE will maintain support of population augmentation in
20 the Upper Missouri River (as revised by the Pallid Sturgeon Recovery Team) and will
21 undertake a series of Level 1 studies aimed at addressing issues related to anoxia in the
22 headwaters of Lake Sakakawea, interstitial hiding of sturgeon free embryos, and drift of
23 free embryos downstream of Ft. Peck, to determine if related management actions might
24 be effective should fish passage at Intake Dam fail to achieve objectives. These efforts
25 follow a decision tree (Figure 10) outlining the strategy for addressing uncertainties and
26 resultant contingent decisions for this reach. Additional NEPA efforts would likely be
27 required before decisions would be made by regulatory authorities to implement other
28 potential actions identified in Figure 10.

* 500 km distance upstream is a coarse guideline because it would provide about 9 days for drift and development under purely passive drift assumptions.

Figure 10. Diagram of a decision tree for contingent information on the Upper Missouri and Yellowstone Rivers (presented as Figure 64 in Chapter 4). Passage at Intake will result in approximately 400 km of drift.

If pallid sturgeon do not successfully spawn on the Yellowstone River but subsequently recruit at sufficient levels, then the ability to manage for spawning on the Missouri River may hinge on whether delayed drift (interstitial hiding) occurs. If it occurs, then potential actions include flow management (low flows), temperature management (increased temperature), or drawdown of Lake Sakakawea. The question of whether delayed drift (interstitial hiding) occurs is important to spawning on the Yellowstone River as well. The necessary upstream migration distance (and hence available drift

1 distance) could be substantially reduced by interstitial hiding. Interstitial hiding is
2 discussed further (see additional discussion in the EA summary, section 4.1.2).

3 Implementation of these other actions would require evidence from related Level 1 and
4 Level 2 studies to suggest that some combination of actions would improve survival to
5 first feeding in the Upper River. Each of the potential actions, with associated
6 hypotheses, objectives, metrics, and decision criteria, are discussed in Chapter 4.

7 **1.4.5 Pallid sturgeon in the Lower Missouri River**

8 Uncertainties for the Lower Missouri River center around how pallid sturgeon use the
9 river, its tributaries, and the Mississippi River. Big Questions relate to possible actions
10 to ensure survival and recovery of pallid sturgeon in the Lower Missouri River (see
11 Table 5). In their framework for pallid sturgeon in the Lower Basin, the USFWS and
12 Corps (2015) identified a suite of four actions anticipated to avoid jeopardizing pallid
13 sturgeon in the Lower River, with associated targets and time limits for implementation
14 (Table 7). The four actions include population augmentation, interception and rearing
15 complexes (IRCs), spawning habitat, and (potentially) manipulation of flows.

16 The uncertainties in the Lower River will be reduced using the framework shown in
17 Table 6. Level 1 and 2 studies are directly tied to those uncertainties and management
18 hypotheses highlighted in the EA that, if resolved, could significantly affect the
19 implementation of management actions. These are presented in detail in Appendix C.

20 The USFWS and USACE (2015) identified a suite of four actions that, subject to the
21 findings of Level 1 and Level 2 studies and further ongoing coordination, that are
22 anticipated to avoid jeopardizing pallid sturgeon in the Lower Missouri River. They also
23 identified targets and defined time limits for implementation of these actions (Table 7).
24 As knowledge is gained from Level 1, 2, and 3 actions, the timeframe for implementation
25 may be adjusted, targets may be changed, management actions may be refined, and
26 hypotheses may be dismissed. The “rules” by which these decisions will be made are
27 outlined in the decision criteria for the respective management hypotheses, subject to
28 the overarching governance and decision process laid out in Chapter 2 of this AM Plan.
29 Chapter 4 of the AM Plan proposes a more accelerated timeline for high priority Level 1
30 actions (implemented in parallel rather than sequentially), as discussed in section 4.3.

31

32

33

1 Table 7. Summary of time limits for implementation and scope of actions.

Action Category	Time Limit*	Minimum Scope	Maximum Scope
Population augmentation	Immediate	Current stocking rate as directed by USFWS Basin-wide Stocking and Augmentation Plan	Variable over time as directed by USFWS Basin-wide Stocking and Augmentation Plan
IRC habitat development	Stage 1 - study phase (years 1-3 post-ROD)	Build 2 IRC sites per year (paired with control sites), adding 33,000 ac-d/yr of suitable habitat, using staircase design ¹ . Assess potential for refurbishing existing SWH sites as IRCs.	
	Stage 2 – continue study phase (years 4–6 post-ROD)	Build 2 IRC sites per year (paired with control sites), adding 33,000 ac-d/yr ¹ of suitable habitat. Refurbish SWH sites in addition to study sites (rate TBD).	
	Stage 3 - Level 3 implementation (years 7–10 post-ROD)	Continue assessing IRC sites and refurbishing new SWH sites, adding at least 66,000 ac-d/yr ¹ of suitable habitat. Determine required rate of Level 3 implementation based on stages 1 and 2.	
	Stage 4 – Level 4 implementation	Remove IRC habitat limitations to pallid sturgeon survival by implementation at Level 4.	
Spawning habitat ²	2 years	1 spawning site	See decision tree in Figure 78
Spawning cue flows	9 years	Requirement for spawning cue flows (and appropriate scope) depends on the outcome of Level 1 and Level 2 monitoring and modeling studies during years 1–9. ³	

2 Notes

3 1. Units of ac-d/year are calculated based on how the flow regime and channel configuration result in cumulative days
4 of availability of suitable habitat during the growing season. Progression through each stage of IRC habitat
5 development is contingent on outcomes and hypothesis tests (USFWS 2016); efforts could be halted if evidence shows
6 that IRCs are not successful. Experimental design for IRC sites, and associated metrics, are described in section 4.2.6.3
7 and Appendix E. Refurbishment of SWH sites into IRCs is described in section 4.2.6.4.

8 2. Anticipated as a Level 2 pilot project focused on developing and evaluating high-quality spawning habitat.
9 Spawning habitat implementation will be guided by the decision tree in section 4.2.6.3 (Figure 78). The evaluation of
10 spawning areas will be based on comparing attraction, egg survival, and hatch to existing spawning areas (see section
11 4.2.6.5).

12 3. See evidentiary framework in Table 48, section 4.2.6.6. Pallid population modeling will be used to set minimum
13 spawning flow needs. Bird impacts and status, reservoir levels, and HC impacts will inform decisions regarding
14 spawning cue flows below Gavins Point Dam in any particular year.

15 At any time during the Framework's implementation, it may become apparent that: (1)
16 a particular action is not needed, (2) a proposed action requires modification to be
17 effective, or (3) that some new action not previously evaluated is required.

18 The artificial propagation program is already taking place at a level having a measurable
19 effect on the population (i.e., Level 3). As knowledge is gained from Level 1, 2 and 3
20 studies, the timeframe for implementation may be adjusted, targets may be changed,
21 management actions may be refined, and hypotheses may be adjusted or rejected. The
22 “rules” by which these decisions are made are outlined in decision criteria for the
23 respective management hypotheses, subject to the overarching governance and decision

- 1 process laid out in Chapter 2. Chapter 4 proposes a more accelerated timeline for high
2 priority Level 1 actions (implemented in parallel rather than sequentially), as discussed
3 in Section 4.3.
- 4 Improvements to address genetic concerns (e.g., maintaining genetic variation similar
5 to the natural population, minimizing threats of hybridization), disease, stocking size,
6 amount of stocking relative to carrying capacity, etc., would be pursued collaboratively
7 with the USFWS and others to be consistent with the Basin-wide Stocking and
8 Augmentation Plan under development by the USFWS. While population augmentation
9 is *necessary* for recovery of the pallid sturgeon, by itself it is not *sufficient* as the ESA
10 requires a self-sustaining population. Augmentation can help severely depleted
11 populations recover numbers of individuals sufficiently to provide reliable evaluations
12 of the effectiveness of alternative actions.
- 13 Level 1 and 2 activities associated with IRCs focus on: (1) the need for additional IRC
14 habitat, (2) refining the relationship between the habitat components and flow (utilizing
15 current operations), and the biological requirements of each habitat type, (3) the needed
16 habitat characteristics and their spatial and temporal distributions, and (4) determining
17 the effectiveness of various mechanical activities and the potential for flow management
18 actions to contribute to future IRC needs. Level 3 actions include physical manipulation
19 of habitats and structures on the Missouri River to create or improve areas having
20 hydraulic conditions to intercept drifting free embryos combined with food-producing
21 habitats and foraging habitats. Actions can be directed at one or any combination of the
22 three components of IRCs. Examples include adjustments to navigation training or bank
23 stabilization structures, channel widening, floodplain modifications or other
24 adjustments to channel geometry, placement of structures to encourage development of
25 needed habitat or habitat complexity, chute development or adjustments to existing
26 chutes, etc. Level 3 actions and outcomes are focused on helping to understand and
27 describe future Level 4 actions and targets, which will be based on bioenergetics
28 requirements of the Missouri River pallid sturgeon population. An experimental design
29 and monitoring plan for IRCs is included in Appendix E of this AM Plan; it involves 12
30 treatment-control pairs implemented over 7 years (see Appendix E).
- 31 The spawning habitat hypothesis (H16) provides an example of application of actions at
32 Level 1 and 2 to reduce critical uncertainties affecting management decisions and
33 targets. An early emphasis will be to utilize information from spawning habitats in the
34 Yellowstone River as the best natural reference condition to inform the design of Level 2
35 pilot projects on the Lower Missouri River, while also continuing to examine the habitat
36 characteristics of spawning sites on the Lower Missouri. Initially only one spawning
37 habitat would be constructed on the Lower Missouri, in a location and form which

1 maximizes the potential for aggregation of males and females. This pilot project will be
2 monitored for effectiveness based on metrics ranging from observed aggregation and
3 spawning to the number of free embryos in the water column (described in section
4 4.2.6.5.5 on metrics).

5 Another example of applying Level 1 research within the Framework is testing the
6 spawning cue hypothesis, H11 (see Table 5). Observational studies (tracking tagged
7 pallid sturgeon movements and spawning over contrasting flow conditions) would), are
8 to be completed during a period of 9 years after the ROD. Analyses of these data and
9 application of an evidentiary framework (section **Error! Reference source not**
10 **found.**) will then be used to determine whether it is appropriate to implement a Level 2
11 action – testing spawning cue flows at Gavins Point. The evidentiary framework will
12 examine the correlations between flows and movement, aggregation, and spawning
13 success, using tagged pallid sturgeon in reproductive condition. Testing hypothesis H11
14 involves both temporal and spatial contrastsKey points and other issues

15 The uncertainties for the pallid sturgeon are both extensive and fundamental to
16 management strategies. Therefore, AM for pallid sturgeon will rely heavily upon
17 research conducted in conjunction with the implementation, monitoring, and
18 adjustments of management actions. This research has been prioritized to focus on
19 critical uncertainties that have a strong influence on decision trees. Early
20 implementation of actions will generally be of an experimental nature (i.e., Level 2) and
21 could involve several concurrent studies that are potentially confounding. This will
22 require careful consideration of what studies will be implemented and when, along with
23 sound experimental designs.

24 **1.5 Human Considerations (HC)**

25 The term Human Considerations (HC) is used in the MRRP to address the interests of
26 all perspectives beyond those of the ESA. These include a wide array of objectives
27 related to the authorized purposes for the System and BSNP (e.g., flood control,
28 navigation, fish and wildlife, irrigation, power, recreation, water supply, water quality)
29 as well as the many other services afforded by the Missouri River. Ensuring the USACE
30 continues to serve all authorized purposes and minimizes impacts to HCs, while still
31 fulfilling the requirements of the MRRP, is a fundamental premise. Several aspects of
32 the AM Plan are geared specifically toward achieving this objective. Chapter 5 discusses
33 how HCs could be considered and monitored during the implementation of a possible
34 AM approach to meeting species objectives for least terns, piping plover and pallid
35 sturgeon (the ESA species) described in previous chapters.

1 **1.5.1 How HCs are considered**

- 2 Section 5.1 provides background on how USACE operates the Missouri River Mainstem
3 Reservoir System and outlines a brief timeline of developments that have led to the need
4 to reconsider operations in the MRRP.
- 5 Section 5.2 outlines how HCs are considered in operational decision making. It
6 summarizes the relationship between the Master Manual, the routine annual
7 operational planning cycle and real time System operational decisions. It describes how,
8 during the development of the MRRMP, long-term implications for HCs of a wide range
9 of alternatives were estimated using various tools and approaches and explored with
10 stakeholders over several rounds of engagement. These are of significance in the present
11 context because they may be of use during the implementation of this AM Plan.
- 12 Section 5.3 discusses the 'Plan and Design' step in the AM Cycle. It summarizes the
13 management actions considered in the MRRMP-EIS and how each can be considered to
14 fall into one of three categories from the perspective of their potential pathways to
15 implementation. It discusses how HCs are given consideration in site-specific planning
16 and in the design of actions under the preferred alternative, as well as how HCs might be
17 considered in planning and design of actions outside the preferred alternative.
- 18 Section 5.4 briefly discusses the 'Implementation' step of the AM cycle from the
19 perspective of HCs.

20 **1.5.2 Monitoring and assessment of HCs**

- 21 Section 5.5 concerns the AM step of 'Monitoring' HC-related issues. It outlines how the
22 USACE currently monitors HC-related issues, the sources of uncertainty in predicting
23 HC impacts and how those sources might be reduced through monitoring. The section
24 discusses the factors future conversations about HC monitoring requirements should
25 consider when identifying and screening specific monitoring actions. It offers a
26 proposed list of candidate HC monitoring studies, along with a possible study
27 prioritization protocol. These proposals and protocol should be thought of as starting
28 points for future discussion, and they require further review and consultation with the
29 HC Team and with the agencies as part of the implementation of the AM Plan.
- 30 The potential monitoring studies to be considered for implementation under the MRRP
31 preferred alternative are introduced and discussed individually. Lastly, monitoring
32 considerations for potential future management actions (i.e., outside the preferred
33 alternative) are discussed on a resource area by resource area basis.

- 1 Section 5.6 discusses the AM step of 'Evaluating' the effects of actions on HCs. It begins
2 with an account of how the HC Team — as one of three AM Implementation Teams —
3 will, on an annual basis, review the current status of relevant HC metrics and indicators
4 (the specifics of which will be determined by USACE and the HC Team as the plan
5 unfolds). It will compare the annual and longer term predictions with monitored
6 impacts to improve future predictive ability. If alternative means of meeting species
7 needs are being contemplated, the consequences for HCs should be considered using an
8 appropriate method and, after trade-offs have been considered, perspectives on
9 implications and recommendations communicated to decision makers.
- 10 Section 5.7 discusses in further detail how decisions under AM might be made in ways
11 that incorporate HC considerations. It again makes the distinction between decisions
12 made within the scope of the preferred alternative and those that would involve the
13 implementation of new actions outside of the preferred alternative and ROD.
- 14 **1.5.3 Further considerations**
- 15 Section 5.8 considers further some of the lessons learned from examination of the
16 MRRMP-EIS alternatives and their effects on HCs. It highlights the specific
17 circumstances under which some of the MRRMP-EIS alternatives are predicted to have
18 disproportionate impacts on HCs. Should any of the flow actions in the MRRMP-EIS
19 alternatives be considered for implementation at a future point in time, this section
20 offers suggestions on how impacts to HCs might be reduced.
- 21 **1.6 Data acquisition, management, reporting and communications**
- 22 AM decisions should be based on "best available science," including information that is
23 relevant, reliable, objective, timely, and accessible, among other attributes. Acquiring
24 and managing the data necessary for the MRRP will be a significant undertaking. An
25 elaborate system is needed just to manage outputs from the dozens of models
26 supporting the program, for example.
- 27 Monitoring of discrete projects spread along more than 1700 miles of river and
28 involving physical, chemical, biological, economic, and social metrics will generate
29 considerable data at varying spatial and temporal scales that must be compiled,
30 classified, subjected to quality control (QC) measures, summarized, transformed, or
31 otherwise analyzed, and stored in a system that permits easy identification and
32 acquisition.
- 33 The successful execution of the MRRP also requires reporting on project performance,
34 System and species status, and communicating Program activities, analysis results, and

1 key decisions to agency personnel, stakeholders, and to the public. Data and analysis
2 results, unless otherwise prescribed by law, should be made available to the decision
3 makers, stakeholders and the public in useful formats.

4

5 **1.6.1 Monitoring and other data acquisition issues**

6 Monitoring plays a critical role in AM applications by providing information needed for
7 learning and to support sound decisions. Choice of which attributes to monitor and how
8 to monitor them (frequency, extent, intensity, etc.) must be linked closely to
9 management actions, decisions, and monitoring purpose. Monitoring must be
10 consistent with the analytical requirements and principles in the evaluation step and in
11 each subsequent step of the AM cycle (see Section 6.1).

12 Monitoring and data acquisition are addressed for pallid sturgeon (see Section
13 6.2.1), birds (see Section 6.2.2), and HCs potentially affected by water and land
14 management actions (see Section 6.2.3). The multi-team approach employed for the
15 MRRP has advantages: consistent approach and sustained expertise; improved agency
16 coordination; and reduced bias. Weaknesses include turnover and inexperience of some
17 personnel, challenges in training and QA/QC procedures, and occasional inconsistency
18 in methods. Future monitoring efforts will build upon the strengths and incorporate
19 measures to address weaknesses.

20 Section 6.2.4 describes a Research data acquisition strategy employing a competitive
21 proposal solicitation process, clear selection criteria, independent peer review, and data
22 submission requirements, and overseen by the ISP to ensure the best return on
23 investment in research and development (R&D).

24 **1.6.2 Data management**

25 Information needs vary at different stages of the AM cycle (see Section 6.1). Users
26 include: agency leadership, MRRIC, the general public, the Management, Fish, Bird, HC
27 and Technical Teams, and researchers (see Section 6.3.1). For optimum learning to
28 occur, a variety of data must be collected in meaningful ways, processed as needed,
29 stored and communicated in accessible formats to serve multiple categories of users,
30 and presented at the right time to assist in decision making (see Section 6.3.2).

31 The goal of the MRRP Data Management System is to provide a single user-friendly
32 access point for MRRP relevant information that is available on a timely basis, in
33 appropriate formats, and meeting required quality standards. Section 6.3 includes

1 specific discussions of users and their needs for information (6.3.1), purpose and
2 objectives of data management (6.3.2), proposed forms of reporting and communication
3 (6.3.3), a proposed plan for developing a data management system (6.3.4), the proposed
4 structure and functionality of a data management system (6.3.5), and a review of
5 existing data management systems (6.3.6).

6 Requirements for the Data Management System are being further defined through a
7 user needs assessment initiated in the fall of 2016. Section 6.3.4 summarizes a proposed
8 Work Plan for developing the Data Management System, involving five phases: (1) a
9 requirements analysis describing in detail the functions and work products that each
10 user group will require, when, and how they will interact with the system (developed
11 through the user needs assessment); (2) a detailed review of systems currently used by
12 MRRP, candidate data portals, and available technologies; (3) identifying
13 implementation barriers; (4) developing a report on system requirements; and (5)
14 prioritized development, implementation, and testing of the Data Management System.

15 Section 6.3.5 describes some of the intended structural features of the MRRP Data
16 Management System and its functionality, and provides examples of these features from
17 existing data management systems. Potential features include: a single portal to
18 information and tools all users; controlled access for certain information and tools;
19 distributed management by the agencies currently generating those data;
20 comprehensive and searchable metadata; and a variety of user-friendly tools to facilitate
21 information access in tabular, graphical, and map-based formats. Existing data
22 management systems, including the Least Tern and Piping Plover Data Management
23 System (TPDMS) and the Pallid Sturgeon Population Assessment (PSPA) Website, are
24 summarized in Section 6.3.6.

25 **1.6.3 Reporting and communications**

26 Communicating results of monitoring and assessment to decision makers involved in
27 the planning and implementation of the MRRP is a primary objective. Others
28 information and communications needs must be met as well, requiring a range of
29 products and information access, potentially including: an online portal for raw
30 monitoring data, data summaries, calendars, maps and other work products; technical
31 reports; draft and final AM reports; system scale AM evaluation reports, technical
32 memos explaining adjustments to management actions, draft and final WPs, fact sheets,
33 journal publications, science blogs and videos; and model manuals. Chapter 6 discusses
34 how these products can be used with the more traditional face-to-face meetings and
35 webinars to meet the Program's communications needs.

1 **1.6.4 Quality assurance (QA) and quality control (QC)**

2 The complexity of the data collection and assessment operations to support the MRRP
3 AMP demands a systematic process for data QA/QC to ensure that decision-makers and
4 stakeholders have confidence that the data they use are scientifically sound, of known
5 and documented quality, and suitable for their intended use. Section 6.4 lays out the
6 basic principles and objectives for a sound QA/QC program, employing the Uniform
7 Federal Policy for Quality Assurance Project Plans (UFP-QAPP) as its basis. All agencies
8 and contractors involved in environmental data acquisition during MRRP
9 implementation are required to adhere to the QAPP.

10 An independent biennial Quality Assurance Review (QAR) will be conducted to provide
11 MRRP management and stakeholders with an assessment of the state of data quality for
12 MRRP. The goals of the QAR are to identify practices that contribute to data quality,
13 identify problems and best management practices, report on the activities of the AM
14 Teams, and recommend improvements to the quality system for MRRP monitoring.

15 Data Quality Objectives (DQOs) have been defined for the MRRP to bring awareness to
16 participants of the minimum data quality required. The DQOs define the type, quality,
17 and quantity of data needed to make defensible decisions. They identify the
18 requirements for field investigations and limits on tolerable error rates, and indicate the
19 intended end use of the data, including decisions that may be made based on the
20 information generated.

21 The ISP, working and coordinating with the various AM Teams is charged with
22 implementation and oversight of the MRRP QA/QC program and will ensure that
23 monitoring adheres to the QAPP. The ISP is responsible for dealing with QA issues,
24 establishing a mechanism for distribution of quality system information and changes,
25 and ensuring data meet or exceed the DQOs of the AMP.

26 **1.7 Summary**

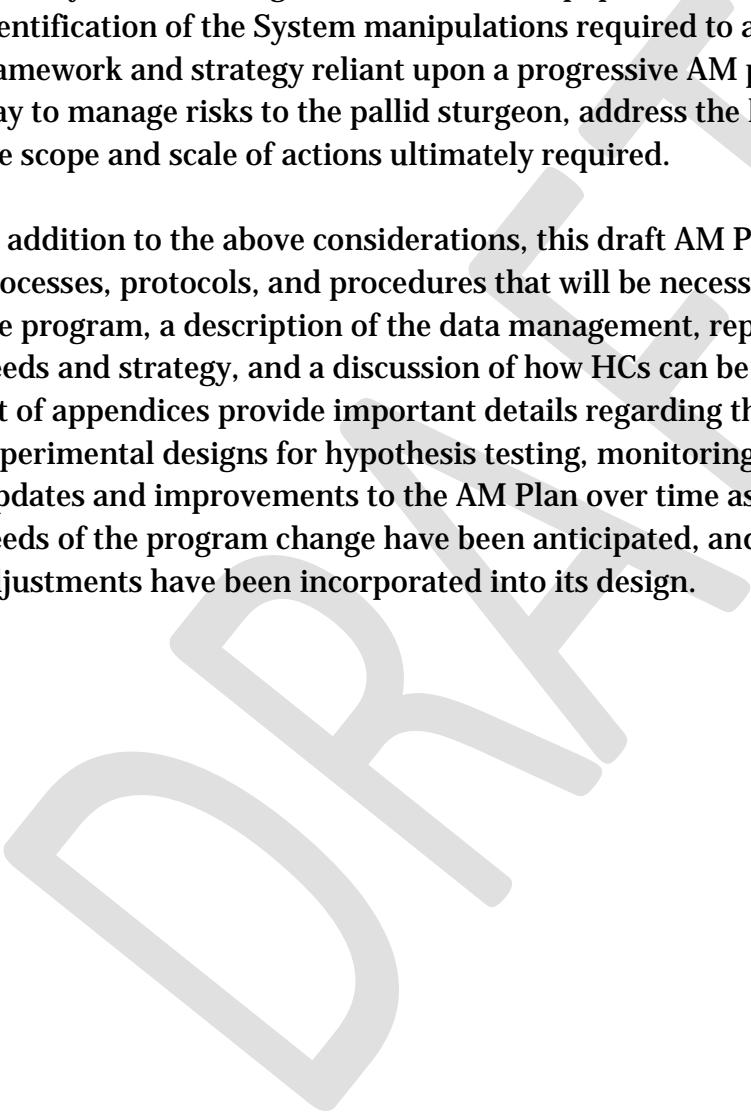

27 Figure 11 illustrates the timeline of events leading to the MRRMP-EIS and this AM Plan.
28 The EA demonstrated that the best available science and current understanding of the
29 effects of the operation and maintenance of the System and the BSNP are not sufficient
30 to clearly identify the scope of actions necessary to avoid jeopardizing the continued
31 existence of pallid sturgeon or its critical habitats. Furthermore, the timing and scope of
32 necessary actions for the piping plover and least tern are uncertain at relevant
33 timescales because of the dynamic nature of those species' critical habitat; predicting
34 needs beyond 1 or 2 years and meeting them within constraints presents challenges and
35 requires trade-offs.

-1985-	<ul style="list-style-type: none"> — May 1985 / Interior least tern listed as endangered species — December 1985 / Piping plover listed as threatened species
1986	<ul style="list-style-type: none"> — 1986 / Section 601 of WRDA 1986 authorizing USACE to develop 48,100 acres of fish and wildlife habitat on public and private lands to mitigate for loss of habitat as a result of the BSNP between Ponca, NE and the mouth at St. Louis, MO.
1989	<ul style="list-style-type: none"> — November 1989 / Missouri River Master Water Control Manual Review and Update Study initiated
-1990-	<ul style="list-style-type: none"> — October 1990 / Pallid sturgeon listed as endangered species
1994	<ul style="list-style-type: none"> — July 1994 / Missouri River Master Water Control Manual Review and Update Study Draft Environmental Impact Statement Published — August 1994 / Draft Biological Opinion on Master Manual DEIS Preferred Alternative Published
1999	<ul style="list-style-type: none"> — 1999 / Section 334 of WRDA 1999 authorizing USACE to acquire an additional 118,650 acres in the Missouri River floodplain to restore or preserve fish and wildlife habitat between Ponca, NE and the mouth at St. Louis.
-2000-	<ul style="list-style-type: none"> — April 2000 / Formal ESA consultation on USACE Missouri River operations initiated — November 2000 / USFWS Biological Opinion published
2001	<ul style="list-style-type: none"> — August 2001 / Missouri River Master Water Control Manual Review and Update Study Revised Draft EIS Published
2002	<ul style="list-style-type: none"> — January 2002 / National Academy of Sciences Report Released
2003	<ul style="list-style-type: none"> — 2003 / BNSP SEIS and ROD — November 2003 / Corps Biological Assessment — December 2003 / Amended USFWS Biological Opinion published
2004	<ul style="list-style-type: none"> — March 2004 / Record of Decision on Master Manual study/EIS
-2005-	<ul style="list-style-type: none"> — 2005 / Spring Pulse plenary sessions — June – August 2005 / Spring Pulse Plenary Group
2006	<ul style="list-style-type: none"> — March 2006 / Master Manual revised to include bimodal spring pulse technical criteria — May 2006 / Gavins Point single spring pulse implemented
2007	<ul style="list-style-type: none"> — 2007 / MRRIC authorized by WRDA — 2007 / Missouri River Recovery Program authorized by WRDA — 2007 / Section 3176 of WRDA 2007 authorizing the USACE to use funds made available for recovery or mitigation activities in the lower basin for recovery or mitigation activities in the upper basin
2008	<ul style="list-style-type: none"> — March 2008 / Gavins Point single spring pulse implemented — July 2008 / MRRIC charter adopted — September 2008 / First MRRIC Meeting
2009	<ul style="list-style-type: none"> — May 2009 / Gavins Point single spring pulse implemented
2011	<ul style="list-style-type: none"> — 2011 / ISAP established by MRRIC/USACE — November 2011 / ISAP Final Report on Spring Pulses and Adaptive Management published
2013	<ul style="list-style-type: none"> — January 2013 / Notice of Intent to prepare an EIS for the MRRMP published in Federal Register — September 2013 / Effects Analysis initiated — September 2013 / Public Scoping period
2014	<ul style="list-style-type: none"> — January 2014 / interim draft conceptual ecological models for pallid sturgeon, least tern, and piping plover — May 2014 / interim draft of working hypotheses linking management of the Missouri River to pallid sturgeon, least tern, and piping plover population dynamics — October 2014 / interim draft of effects analysis integrative reports for pallid sturgeon, least tern, and piping plover
-2016-	<ul style="list-style-type: none"> — April 2016 / Draft MRRMP-EIS published

- 1 Given the uncertainties identified by the EA, the lead agencies deemed it prudent to
2 proceed by identifying a Preferred Alternative in the MRRMP-EIS that addresses the
3 priority hypotheses from the EA, but to also prepare an AM Plan that provides the
4 framework, performance standards, decision criteria, and governance processes needed
5 to guide the MRRP's implementation so that knowledge gained over time would
6 translate into refinements of or adjustments to the management actions necessary to
7 meet the Program's objectives.
- 8 In lieu of a more definitive but comprehensive set of actions that might have otherwise
9 been prescribed, the AM approach provides (a) time and latitude to implement, monitor
10 and assess actions in a structured fashion to promote learning, (b) opportunities for
11 research and studies that may yield answers to critical questions more quickly than
12 would occur through implementation alone, and (c) the flexibility to reject, modify, or
13 introduce new actions and/or adjust targets based on knowledge gained through the
14 process. This approach recognizes the trade-offs between time and knowledge, and
15 balances the risks and uncertainties so as to benefit of the species, while minimizing
16 costs and impacts.
- 17 The AM strategy builds upon the products of the EA, employing rigorous hypothesis
18 testing, project and Program monitoring and assessment, and predictive numerical
19 modeling of habitat, species status and effects of alternative management actions. A
20 science update process affords decision-makers needed information to make annual
21 update to a 5-year strategic WP for the MRRP. Annual updates may include adjustments
22 to plans for the current and next FYs, but are focused on the FY+2 Program to align with
23 the USACE's Civil Works budget needs.
- 24 Interagency Bird and Fish teams that include MRRIC WGs use information generated
25 by a non-decisional Technical Team to formulate recommendations and prioritized
26 actions for each species. An HC Team reviews monitoring and assessment results as
27 they relate to effects of actions on HC interests and provides recommendations for
28 related needs. An interagency Management Team drafts adjustments to the WP using
29 the Bird/Fish/HC Team recommendations and guidance regarding resource availability.
30 Draft updates to the WP are vetted through engagements between the lead agencies and
31 MRRIC at plenary meetings that provide opportunities for input, collaboration, and
32 consensus recommendations. The same process is used to address adjustments to the
33 Program's governance, to resolve disputes, etc.
- 34 Managing for the birds involves meeting targets for ESH while minimizing impacts to
35 authorized purposes, balancing other Program needs, and accounting for constraints.
36 The challenge lies in uncertain future conditions regarding system runoff and

- 1 operations, which affect habitat availability and population responses. The habitat and
2 population models provide powerful tools to support management decisions. AM
3 opportunities center on improvements to these tools, better and more cost-effective
4 methods for creating and maintaining ESH, and predator and vegetation management.
- 5 Managing for the pallid sturgeon presents more significant challenges. Uncertainties
6 regarding the specific factors causing recruitment failure for pallid sturgeon and the
7 inability to link management actions with population response prevent the clear
8 identification of the System manipulations required to address the species' needs. A
9 framework and strategy reliant upon a progressive AM program is the most effective
10 way to manage risks to the pallid sturgeon, address the key uncertainties, and identify
11 the scope and scale of actions ultimately required.
- 12 In addition to the above considerations, this draft AM Plan includes a number of
13 processes, protocols, and procedures that will be necessary for the implementation of
14 the program, a description of the data management, reporting and communications
15 needs and strategy, and a discussion of how HCs can be addressed. An accompanying
16 set of appendices provide important details regarding the needed research,
17 experimental designs for hypothesis testing, monitoring and assessment protocols, etc.
18 Updates and improvements to the AM Plan over time as understanding grows and the
19 needs of the program change have been anticipated, and processes for periodic
20 adjustments have been incorporated into its design.

21

21 **Governance of the AM Program**

2 Chapter 2 addresses the governance of the MRRP AM Plan –the management and
3 decision making structure and process for the program – and describes several
4 important principles and attributes of good governance. The range of decisions required
5 for the plan development and its implementation are discussed in Section 2.2. The roles
6 and responsibilities of the primary entities involved in governance are described in
7 Section 2.3. The decision process, and in particular the interactions occurring around
8 the development and update of the WP are discussed in Section 2.4. The chapter
9 concludes with a presentation of several important protocols and procedures (see
10 Section 2.5). The decision making structure contained in this section is in no way
11 delegation of decision making authority. Nothing in this section is designed to impede or
12 infringe any statutory decision making authority for any party described.

13 **2.1 Definition, principles and key attributes for effective governance**

14 **2.1.1 Governance defined**

15 Although several definitions of governance are available, a broadly held view is that it
16 includes a consideration of authority, administration, decision-making, and
17 accountability. Governance for an AM program describes the approach for converting
18 knowledge into improved management through decision making, including:

- 19 • **what** decisions need to be made,
20 • **who** is involved in the decision process,
21 • **how** decisions are made, and
22 • **when** decisions are required.

23 The concept of “adaptive governance” has recently emerged in the context of AM, adding
24 consideration of the need for organizational and institutional flexibility to change, which
25 is a crucial concern for the MRRP AMP given the likelihood that the governance strategy
26 will need to be adjusted to suit program needs, and that the lead agencies and MRRIC
27 will also need to adjust to this way of doing business.

28 **2.1.2 Attributes of governance that enable AM**

29 Although AM has been applied to natural resource management for several decades,
30 implementation has not been easy. Obstacles include concerns that implementing and
31 rigorously evaluating management actions different from the status quo may be too
32 costly, too risky, and/or contrary to values of some stakeholders, as well as perceptions
33 that a shift to AM threatens existing management, research and monitoring programs.

1 Effective governance can help address these obstacles by acknowledging differences in
 2 values/policies (i.e., What do you want?) from alternative beliefs about causation (i.e.,
 3 How do you get it? See Lee [1993]). The ideal setting for AM is one in which there is
 4 agreement around the objectives and policies, while allowing for disagreement around
 5 the cause and effect of different approaches. Because it cannot always be avoided, a good
 6 AM program should also have processes for resolving value-based conflict.

7
 8 Effective systems of governance and organizational networks for AM serve several
 9 functions, including: (1) trust-building, (2) knowledge generation, (3) collaborative
 10 learning, (4) preference formation, and (5) conflict resolution (Green et al. 2015). A
 11 robust system of governance that can execute, innovate and learn is preferred for AM
 12 (Duit and Galaz 2008). Attributes that enable AM can be divided into three sequential
 13 and mutually supportive subsets (Greig et al. 2013). Governance first requires
 14 mechanisms of conflict resolution and trust building. Attributes related to problem
 15 definition, communication, leadership, executive direction, and organizational structure
 16 are the second set of critical elements to establish. If done well, the third set of attributes
 17 will follow: community involvement, planning, funding, staff training, and AM science.
 18 Table 8 summarizes factors enabling and inhibiting good AM governance.

19
 20 Table 8. Factors enabling and inhibiting good governance of AM programs.

Factors Enabling Good Governance	Factors Inhibiting Good Governance
Collaborative, interdisciplinary working environment with free-flowing communication and easy access to well-synthesized information.	Communication among components/departments hindered by different mandates or between disciplinary specialists (i.e, stovepiping). Difficult to access required information.
Frequent re-examination of management and restructuring as needed.	Management done the same way for a very long period of time.
Leaders deliberately challenge themselves and staff to recognize change, innovatively adapt to challenges, and take calculated risks.	Leaders resist change, discourage risk and innovation, and create organizational culture of status quo.
Collaborative inputs to decision making over sustained period, generating buy-in and trust, allowing stakeholders to move from positions to interests, clarifying areas of agreement and disagreement.	Institutions isolated from public/stakeholders; very limited and inconsistent consultation. “Inform” rather than listen.
Recognize critical uncertainties and plan experiments to test alternative hypotheses/actions.	Plan based on past experience, practices, procedures established by senior staff.
Stress high-quality science at appropriate scales, with independent review panels. Data made available; different interpretations of data welcomed, used to postulate alternative hypotheses and design management experiments. Wide publishing of scientific findings.	Science discouraged or use of “advocacy science” to support agency’s position (see Section 2.1.3). Data kept internal; selective evidence used; insist on single, dogmatic agency position regarding data analysis.

1 There is no “one-size-fits-all” approach to effective governance. An effective system will
2 depend on the intended purpose/need and will have clear expectations around
3 outcomes (Rijke et al. 2012). Although lessons can be learned from other AM programs
4 (e.g., Trinity River, Platte River, Glen Canyon), an effective system of governance for the
5 Missouri River requires consideration of how the above attributes and functions apply
6 within the context of the unique ecological and social conditions for the Missouri Basin.
7

8 The MRRIC (2011) indicated that the engagement approach for developing and
9 implementing an AM strategy should:

- 10
- 11 • be understood and trusted by MRRIC members
 - 12 • provide a satisfactory level of participation in the systematic process for MRRIC
 - 13 members as well as provide
 - 14 • afford opportunities for MRRIC to identify any social, economic, or cultural issues
 - 15 that may result from the proposed action(s)
 - 16 • be implementable for both the agencies and MRRIC
 - 17 • be focused on resolving scientific uncertainties necessary to inform management
 - 18 decisions
 - 19 • provide for collaboration that allows the agencies to implement the MRRP in a
 - 20 timely manner.

21 Gunderson and Light (2006) point out that the Comprehensive Everglades Restoration
22 Program has been hindered by long standing feuds among special interest groups
23 (agricultural and environmental) who seek certitude in policy, rather than
24 understanding through experimentation. AM accepts that “failures” will occur and that
25 those failures provide a valuable contribution to learning; other approaches seek to
26 avoid policy failure, which reinforces the status quo and precludes opportunities for
27 learning while doing (Blann et al. 2003; Light, 2001). Governance must recognize that
28 short-term “failures” are critical to long-term success.

29 To be successful, AM must be applied under and supported by a governance structure
30 that understands AM, values it, and is willing to commit the necessary resources to
31 allow its processes to work (Loftin 2014). AM and accountability are closely linked; both
32 answer questions about whether progress is being made using ecosystem and program
33 information (Puget Sound Partnership 2008). While the USACE is ultimately
34 accountable for executing the program so as to avoid jeopardizing the listed species or
35 their habitats, each of the entities involved in the MRRP must be accountable for their
36 roles in executing the plan. The use of performance metrics, decision criteria, and other
37 triggers can improve accountability (Nie and Schultz 2012) and are therefore
38 emphasized in this plan.

- 1 Fischenich (2012) indicated that AM works best when (a) management flexibility is
2 incorporated into the design and implementation of programs or projects; (b) projects
3 and programs can be implemented in phases to allow for course corrections based on
4 new information; (c) interagency collaboration and productive stakeholder participation
5 are fostered; and (d) scientific information is introduced into the decision-making
6 process and guides managers not only during planning, but also after project
7 implementation.
- 8 Governance can take several forms. The “governance” implicit in the decision criteria,
9 contingency plans, and other guidance incorporated into the AM Plan, which are
10 decisions agreed upon prior to implementation, are as important as the governance that
11 occurs through post-implementation decisions. A recent review of court decisions
12 (Fischman and Ruhl 2016) suggests they are an essential component of an AM Plan.
- 13 **2.1.3 Ensuring objective and reliable science in the Missouri River Recovery Program**
- 14 AM requires reliable information for improved decision making, increased effectiveness
15 of management actions, and increased ability to meet program objectives. Decision
16 makers and stakeholders must be confident that the underpinning science is unbiased
17 and sound. The utility and credibility of science is reduced when influenced, or
18 perceived to be influenced, by agendas, political pressures, advocacy, and bias. This is a
19 common challenge among science programs and especially for those involving
20 contested, controversial, or politically-charged topics. Scientists must adhere to, and
21 organizations must promote, practices and conduct that contribute to the best available
22 scientific data and information, and generate objective, relevant information for
23 decision makers.
- 24 The MRRP Integrated Science Program (ISP) relies on partner agencies to conduct
25 research and monitoring, analyze data, and report findings. An advantage of this
26 approach is that significant expertise –often not available elsewhere– exists within these
27 agencies. Work conducted by multiple partners can benefit from the broad perspectives
28 those partners provide. However, partner agencies have their own missions and, in
29 some cases, advocacy roles. For the MRRP, scientists must follow scientific codes of
30 conduct and accurately report findings, even when results do not support agency
31 positions. Potential conflicts of interest and unsound scientific practice must be
32 identified and addressed to prevent their influence on the scientific data and
33 information used in the MRRP. Agency leadership, scientists, independent advisors, and
34 stakeholders all play important roles in addressing this concern.
- 35 The potential for bias is ever present and guarding against it by relying upon the
36 Program’s ability to identify and engage only unbiased entities is not an effective

1 solution. Because even the perception of bias will undermine credibility and ultimately
2 the utility of science, the solution must be broad, transparent, confidence-building, and
3 continually monitored for effectiveness. The following mechanisms will be employed to
4 help minimize bias, increase transparency, build confidence among agency decision
5 makers and stakeholders, and ultimately maximize the credibility and usefulness of the
6 data and knowledge underpinning decisions for the MRRP:

- 7 1. **Embrace independent review.** Independent review, (e.g. ISAP and external peer
8 review) provides opportunity for critical, independent, and transparent evaluation of
9 experimental designs, science findings, interpretations, and resulting decisions.
10 Independent review, especially when performed transparently with opportunity for
11 engagement by interested parties and open scientific deliberations, serves to
12 dramatically increase trust in a science program. Successful use of independent
13 reviews requires commitment by scientists, stakeholders, and decision makers to
14 embrace the process. In addition to these reviews, subjecting MRRP science to peer-
15 review and publication standards is important and should be a requirement of
16 scientists working on the MRRP.
- 17 2. **Engage expertise within and outside the basin.** When little scientific input or
18 interaction occurs among scientists within and outside the basin (e.g., those studying
19 pallid sturgeon on the Mississippi River, other sturgeon species, or other highly
20 altered river restoration efforts), science efforts can become myopic or suffer from
21 lack of perspective and lessons learned by others. This is especially true for pallid
22 sturgeon and piping plover science efforts given that these species occur and are
23 extensively studied outside of the Missouri River basin. Recurring, structured
24 interactions among system- and subject-matter experts both within and outside the
25 basin, including Recovery Teams, will ensure that science efforts are coordinated,
26 well-informed, and considerate of relevant knowledge and expertise.
- 27 3. **Diversify partnerships and increase reliance on a competitive proposal process.**
28 Striking the proper balance between the need for consistency and development of
29 expertise with the benefits of new partnerships and additional scientific perspective
30 is a challenge for any program. The ISP and MRRP should, where practical, seek to
31 involve new science partners and pursue proposals for research efforts through
32 competitive processes that generate alternative strategies, foster new collaborations,
33 and bring innovative concepts to bear upon the challenges of the MRRP. Because the
34 Program is hypothesis based, scopes of work can be clearly defined, creating a
35 competitive proposal process with several inherent benefits.
- 36 4. **Maximize transparency.** It is critical that the ISP and all parties to the MRRP
37 continue to function transparently, ethically and openly. Maximum transparency
38 regarding collected data, analyses, scientific deliberations, recommendations, and
39 science prioritization should remain a priority. Continued emphasis on frequent and
40

1 effective communication is necessary. To this end, the development of a web-based
2 data management and reporting system should be a near-term programmatic
3 objective (see Section 6.3).

4

5 5. Predefine data collection and analyses requirements and follow the plan. Clearly
6 defined procedures in the AM Plan increase transparency and reduce opportunities
7 for bias. Monitoring and assessment protocols must be followed, related analyses
8 completed, and results shared, regardless of the findings. Scientists cannot have the
9 opportunity to selectively analyze data or report only those findings consistent with
10 the scientist's or agency's aims. Acceptable monitoring, assessment, and analytical
11 practices, as driven by program needs, will be identified and incorporated into the
12 AM process through compulsory protocols published in the AM Plan and identified
13 in any work orders or contracts.

14

15 6. Optimize institutional structure to minimize conflict between policy and science. The
16 ISP cannot act or be perceived to filter information so as to support an agency
17 agenda. Instead, the role of the ISP must be to ensure that sound scientific processes
18 are followed, that appropriate checks and balances are in place to counter inherent
19 bias, and that all relevant information is considered and evaluated. To this end,
20 structuring of the MRRP should provide confidence that science practice is clearly
21 separated from undue influence of advocacy and peripheral agendas.

23 **2.2 Decision needs for adaptively managing the MRRP**

24 Planning, implementing, and adaptively managing the MRRP requires hundreds of
25 decisions ranging from relatively mundane issues like what type of net to use for
26 sampling to significant and potentially contentious issues like whether to adjust flow
27 releases from a reservoir to create habitat. Decisions occur at many points in the
28 process; they are made, for example, when setting or updating goals and objectives,
29 when selecting actions to implement and how they should be monitored, and when
30 determining if or how to adjust the strategy due to new information.

31 The USACE Commander for the Northwestern Division (NWD) is ultimately responsible
32 for most of these decisions. However, the sheer volume of decisions demands that many
33 decisions be delegated to the District Commanders or others within the agency.
34 USACE's senior leadership cannot be involved in all the day-to-day technical activities of
35 the Program, so they must rely upon recommendations from subordinate staff familiar
36 with the issues and from subject-matter experts engaged by the MRRP for that purpose.
37 They also rely upon input from MRRIC, other agencies, Tribes and the public, where
38 appropriate, when making decisions. The USACE has a long history of operating in this
39 fashion, which is an important consideration when developing a governance structure
40 for the MRRP.

- 1 The USFWS is responsible for compliance-related decisions, including policy
2 determinations regarding the application of AM to the ESA. As knowledge about species
3 and their responses to management is gained through implementation, it may be
4 necessary to adjust the targets, decision criteria, and/or required management actions
5 in order to sustain a determination that the operation of the System and BSNP is not
6 likely to jeopardize the listed species or their habitats. The USFWS Mountain-Prairie
7 and Midwest Regional Directors will work closely with the USACE, MRRIC, and the
8 other entities listed above when making these decisions.
- 9 MRRIC shares responsibility for the Program performance; their input and
10 recommendations influence agency decisions. MRRIC may provide a consensus
11 recommendation regarding the Program's governance; if all parties agree to the rules of
12 engagement, the potential for conflict is reduced. AM demands the commitment of time,
13 resources, and active engagement of stakeholders, as well as their commitment to
14 actively engage in the governance process and provide the necessary input to decision
15 makers.
- 16 Importantly, certain parties are explicitly excluded from decision-making roles.
17 Facilitators promote group participation, trust, mutual understanding, and shared
18 responsibility for decisions, but are not themselves decision makers, so must maintain a
19 neutral posture on any decision. Similarly, technical experts play an important role by
20 helping to link objectives and management decisions to system understanding, but are
21 not themselves stakeholders, so should not be involved in objective/value development
22 or decision making. These entities must be viewed by agencies and stakeholders as
23 neutral third parties, and must be capable of performing as such (see Section 2.1.3).
- 24 **2.2.1 Scope of decisions in the MRRP**
- 25 The most evident and essential function of governance for an AM program is to facilitate
26 effective, transparent decision making. However, decisions for the MRRP (and all other
27 large-scale, ecosystem-based programs) are complicated by several important legal,
28 social, political, and economic dimensions. The design of the Program's governance
29 structure and processes must, therefore, anticipate the wide range of decisions needed
30 to translate knowledge gained about the system and species into effective and acceptable
31 management. Governance design should also promote decision making at the lowest
32 practicable level and be sufficiently flexible to allow for efficient, timely decisions,
33 accommodate unanticipated decision needs, and to grow/change with the Program.
- 34 Attachment 16 of Appendix A includes a table with examples of the decisions required to
35 adaptively manage the MRRP. The decisions in the table are posed in the form of
36 questions, which are categorized based on the activity to which they apply. The table

- 1 includes the point in the process at which the decision for each question is needed (i.e.,
2 which step of the AM cycle and the program entity generally responsible for making
3 recommendations on each decision as well as the entity that would typically make the
4 decision. Some of the organizational elements listed in the table have not been
5 previously described in thisAM Plan (see Section 2.3 for descriptions of entities
6 involved). Many more decisions will be required than those listed, and some situations
7 that may not be encountered are described because they present challenges better
8 addressed during Program development than during execution, when time may be
9 limited or perspectives complicated by other factors.
- 10 Because of the large number of questions and the need to delegate, decisions for the
11 Program may be made at three general levels of authority within the agencies (defined
12 herein as Oversight, Management and Implementation).
- 13 1) The Oversight level includes agency senior leaders, who are responsible for decisions
14 related to Federal policies and protocols, the setting of objectives and targets for the
15 Program, and developing protocols for maintaining compliance with the ESA and
16 other mandates. Additionally, Oversight is required for establishing the Program's
17 governance structure and processes, operating procedures, and criteria for changing
18 the above. They also decide the decision space in which the program operates and
19 how it is implemented (e.g., which management actions are included and to what
20 extent). Decisions at this level may significantly affect stakeholder interests or
21 authorized purposes, and therefore involve collaboration with the MRRIC. These
22 decisions are primarily made during the Plan/Design step (Step 1) of the AM cycle as
23 the Program is developed, but are revisited periodically and as needed during the
24 Adjust/Continue step (Step 5).
- 25 2) The Management level, which includes agency program managers (PMs), the ISP
26 Manager, and others in similar positions. Management develops the draft WP for the
27 Program with guidance from agency senior leaders. They also manage and, where
28 authorized, make selected decisions regarding several aspects of the Program's
29 implementation, including resource allocation, reporting and communication, and
30 collaboration. They make recommendations on needed changes to the Program's
31 operations and structure, and oversee the implementation of those changes with
32 approval from the Oversight level. MRRIC provides input to the WP and may make
33 recommendations regarding any management-level decisions or processes.
34 Management-level decisions are primarily made at the Plan/Design and
35 Implementation steps (Steps 1 and 3) of the AM cycle, but can include decisions at
36 each step of the process, and are frequently required as part of the Program's
37 operations (e.g., annually).

- 1 3) Implementation-level decisions include the wide ranging and numerous judgments
2 needed for the day-to-day operation of the Program. These include how monitoring
3 programs are implemented, how assessments are conducted and reported, how
4 projects are implemented, etc. Note, however, that the real-time flow management
5 decisions made by the Corps' Water Management Division following the procedures
6 and requirements in the Missouri River Mainstem Reservoir System Master Water
7 Control Manual are Oversight-level decisions (see Section 2.3.1).
- 8 Decisions occur at each point in the AM cycle (see Figure 5), but tend to cluster by
9 category and authority level, and are especially abundant at steps 1 and 5.
- 10 1) During the assessment and plan/design step, (Step 1), decisions must be made at all
11 levels about the scope of the program and how it will be implemented and adjusted.
12 These include policy and process decisions establishing objectives and targets,
13 decision space and criteria (which actions will be implemented, and how) and
14 processes for making decisions and communicating outcomes. The initial phase of
15 this step (assessment) was largely addressed by the EA and the MRRMP-EIS, leading
16 to the establishment of the ROD and thisAM Plan. The assessment phase as defined
17 (and not to be confused with the evaluation step) is needed only infrequently, having
18 last been undertaken in 2003. The plan/design step is frequently revisited (typically
19 annually), however, to ensure the actions implemented are effective and needed
20 adjustments are made following procedures in the Plan's Governance section.
- 21 2) During the Implement step, (Step 2), decisions center around research activities, the
22 actions being implemented, needed adjustments due to unanticipated conditions in
23 the field (e.g., high river stage preventing habitat construction) or needed
24 adjustments to enhance effectiveness or minimize impacts. These decisions must be
25 made quickly and are therefore supported by real-time monitoring, modeling,
26 contingency plans, and other mechanisms for improving efficient information flow.
- 27 3) Few decisions are made during the Monitor step; (Step 3); monitoring teams should
28 not deviate from established protocols. However, some decisions during monitoring
29 may be necessary to address unusual conditions. To the extent practical, contingency
30 plans that maintain needed statistical rigor but permit altered sampling methods
31 should be developed to address unusual, but not entirely unanticipated conditions or
32 events (e.g., floods, drought, etc.).
- 33 4) Decisions are not generally made during the Evaluate step; (Step 4); rather, this step
34 prepares information for decisions in Step 5 (complete/adjust/continue). The need
35 for adjustments to processes, protocols, models, etc., may become evident in the

1 course of conducting evaluations and result in recommendations to advise decisions
2 regarding changes to those plan components, but decisions to make those changes
3 would typically occur independently of the time during which evaluations are
4 underway.

- 5 5) Most decisions occur in the Complete/Adjust/Continue step (Step 5). Decisions may
6 be made to (a) continue actions as planned or previously implemented; (b) adjust
7 how the actions are currently implemented actions are carried out; (c) adjust which
8 actions in the selected alternative are implemented; (d) adjust which actions are
9 included in the selected alternative (adding or removing actions, or expanding
10 definitions beyond what is currently included). Decisions may also be made at this
11 stage to continue or adjust programmatic or policy components as specified in the
12 initial Plan/Design phase (Step 1). In this last case, all or part of Step 1 may be
13 repeated to reformulate the plan as needed.

14 **2.2.2 Balancing needs for the birds and fish**

15 Because objectives and management actions have been identified separately for the
16 birds and fish, the potential exists for actions aimed at one species to adversely affect the
17 other; they can also synergize with or have no measureable influence on the others. A
18 key stage in the planning of actions is the assessment of their effects on the target
19 species, on other species, and on the various HC interests. Where possible, actions
20 should be adjusted to avoid and minimize adverse effects and to maximize benefits.
21 Actions with unavoidable adverse impacts should be judged against associated trade-
22 offs and other alternatives.

23 Overlapping effects are substantially reduced by geographic realities; aside from that
24 portion of the Southern Region for the birds downstream of Gavins Point Dam, the
25 targeted areas for the birds and fish do not coincide. Direct and localized secondary
26 effects of habitat construction – the focus of the preferred alternative – are therefore
27 generally restricted to the target species (see further discussion in Sections 3.2.5 and
28 4.2.6.7). The greatest opportunity for intersecting effects occurs with flow management
29 actions. A spring release aimed at pallid sturgeon spawning, for example, might create
30 some emergent sandbar habitat but might also delay bird nesting (see Section 3.2.5).

31 Potentially overlapping effects of management actions are considered at several stages
32 in the process. The initial set of actions included in the preferred alternative, as well as
33 the other actions considered in the full range of alternatives, were evaluated in detail as
34 part of the MRRMP-EIS process (see Chapter 4 of the EIS and Sections 3.2.4 and 4.2 of
35 this AM Plan). Similar analyses will be conducted by the USACE and/or the Technical
36 Team for any new management actions identified in the future, and the cumulative

1 effects of all management actions will be assessed as part of the WP formulation process
2 whenever new actions are proposed (see Section 2.4.5). Management actions should be
3 optimized at the concept and design stages to avoid and minimize impacts (or optimize
4 benefits vs. impacts), and adjusted as needed during the WP formulation to ensure their
5 performance as part of a suite of management actions is consistent with objectives.

6 Whereas potentially overlapping effects of management actions are few and infrequent,
7 balancing the needs for bird and fish in terms of Program focus and budget will remain
8 an ongoing requirement. For pallid sturgeon, the research and implementation strategy
9 needed to overcome critical uncertainties could fully exploit available Program
10 resources. However, the extent to which the Program focuses on pallid sturgeon needs
11 will likely be driven by habitat requirements for the piping plover. Historical patterns of
12 runoff and System storage – which will presumably continue – have resulted in periodic
13 high flows (e.g., 1952, 1975, 1997, and 2011) that create abundant ESH. These events are
14 typically followed by periods of declining ESH acreage as the sandbars erode under
15 normal operations. When the acreage approaches or drops below targeted levels,
16 construction will be needed to offset losses and maintain sufficient habitat for the birds.

17 Balancing bird and fish needs that differ over time requires ongoing analysis, planning,
18 risk management, and flexibility. Program resourcing (budget and personnel) will need
19 to be periodically shifted to address changing requirements. The need for additional
20 ESH will seldom be a surprise; erosion rates are reasonably predictable, and modeled
21 acreage projections can be used, to some degree, to identify when shortfalls are likely.
22 Conversely, shortfalls can be abated by an unforeseen high flow event, requiring
23 decisions about alternative use of funding intended for ESH construction and personnel
24 assigned to that purpose. Moreover, decisions about when to begin ESH construction as
25 habitat acreage declines, and how much to build in any year, can be a challenge
26 involving weighing the risks of not meeting targets and required trade-offs in terms of
27 lost opportunity for pallid sturgeon research or project implementation. Management
28 decisions that properly balance these considerations should improve over time, applying
29 the best combination of a) variable budgets that reflect ESH needs, b) trade-offs
30 between the birds and fish, c) occasional use of flows to meet ESH targets, d) acceptance
31 that targets for one or both species may not be met at times, or e) some as yet
32 unforeseen approach.

33 **2.2.3 Timing of AM decisions**

34 Though dramatic shifts in the strategy or emphasis of the MRRP can occur based on
35 new information, changes in system status, or unanticipated budget adjustments.
36 However, change is more likely to be infrequent and slow. Testing of the EA hypotheses
37 requires the exercise of rigorous experimental designs that can take 5 to 10 years before

- 1 trends are evident and decisions about the effectiveness of a management action
 2 effectiveness can be made with any confidence.
- 3 Additionally, several processes outside the MRRP impose important constraints on the
 4 development and implementation of the WP. The Compliance with policies that apply
 5 to elements of the MRRP affects scheduling and execution of the Program (Figure 12),
 6 though the most significant Program constraint is the Corps' annual budget process for
 7 Civil Works and the development of the Annual Operating Plan (AOP) for the Missouri
 8 River Mainstem Reservoir System. USACE Civil Works funding is a two-year
 9 development process that can be generally summarized as a develop-defend-execute
 10 cycle. The Corps budgets and executes its mission on an FY basis. The FY begins
 11 October 1 and ends September 30 the following year. Using January 2017 (FY17) as a
 12 starting point, the schedule for development of the FY19 budget is shown in Table 9.
- 13 The above realities dictate a “strategic” rather than a “tactical” approach to managing
 14 the MRRP. Activities within the current Fiscal Year (FY) or the next FY (or FY+1) may
 15 be subject to minor adjustment only given the budgets are already fixed, actions
 16 planned, and mechanisms to shift those actions limited. Emphasis should therefore be
 17 placed on establishing needs to set the future Program and budget. Defining needs for
 18 the FY+2 Program and budget, in particular, should be the focus of the agencies and
 19 MRRIC on an ongoing, annual basis. Given the USACE’s Civil Works budget process, the
 20 Program should be aligned to define those needs no later than June and preferably
 21 earlier in any year.

- 22 Figure 12. Timeline for budgeting, strategic review, WP development, and the AOP.
- 23 2.2.3.1 *Federal water resource budgeting*
- 24 Funding availability profoundly affects the ability to execute the MRRP. The year-round
 25 budget process engaged in by the USACE and other Federal agencies occurs on a
 26 timetable that affects other considerations in the AM Plan.
- 27 Congress generally authorizes numerous new USACE site-specific activities and
 28 provides policy direction in an omnibus USACE authorization bill, typically called the
 29 Water Resources Development Act (WRDA) or more recently the Water Resources

- 1 Reform and Development Act of 2014 (WRRDA 2014; P.L. 113–121). The WRDAs do not
 2 provide funds to conduct activities, nor are they reauthorization bills. Federal funding
 3 for USACE civil works activities is provided in annual Energy and Water Development
 4 appropriations acts or supplemental appropriations acts.
- 5 USACE Civil Works funding is a 2-year development process that can be generally
 6 summarized as a develop-defend-execute program cycle. The USACE budgets and
 7 executes its mission on an FY basis. In the absence of congressional passage of an
 8 agency-specific appropriation, Civil Works annual funding is generally included in an
 9 all-encompassing "omnibus" bill. If a bill has not passed at the start of the FY, Congress
 10 typically passes a Continuing Resolution Authority (CRA), which allows the USACE to
 11 continue operations until such time as an appropriations bill is passed or the CRA
 12 expires. Under a CRA, funding is typically provided on a month-to-month basis (or
 13 other similar timeframe) based on the previous year's funding level. Table 9 provides an
 14 example of the budget cycle, beginning with budget guidance for FY2019, which is
 15 provided in January of 2017.

16 Table 9. Schedule for the USACE's Civil Works budget development process.

Month / Year	Budget task and responsible parties
JAN 2017	Office of Management and Budget (OMB) provides budget guidance for FY19.
MAR/APR 2017	Headquarters USACE (HQUSACE) provides FY19 budget limits and program guidance within the USACE based on the OMB and additional ASA (Civil Works) guidance.
MAY/JUL 2017	USACE field offices develop FY19 program requirements based on the USACE guidance.
JUL 2017	HQUSACE reviews the field-developed FY19 requirements.
JUL/AUG 2017	The USACE-developed FY19 budget is worked with the Secretary of the Army.
SEP 2017	The Army's FY19 budget program is submitted for OMB review.
SEP-NOV 2017	OMB reviews with and then tells Army and the USACE what its budget will be for Civil Works program planning in FY18. This is referred to as the OMB passback.
DEC-FEB 2017/18	The President's budget for FY19 is finalized and submitted to Congress. It provides the USACE with the specific budget details needed to plan FY18 Civil Works program execution.
FEB-MAY 2018	Congress conducts appropriations (and, if necessary, authorization) hearings to discuss and ask detailed questions about the President's FY19 budget submission. The Assistant Secretary of the Army (Civil Works) and USACE leadership testify before subcommittees to address Congressional concerns about the President's budget for the FY19 Civil Works program.
JUN-SEP 2018	Appropriations bills for FY19 are developed and approved by Congress.
SEP/OCT 2018	President signs the FY18 appropriations legislation into law. The legislation provides the USACE with specific Civil Works program execution guidance by funding category and specifically authorized projects and studies.

OCT/DEC 2018	HQUSACE allocates FY19 funds within the USACE for FY execution.

1

2 **2.2.3.2 Annual Operating Plan (AOP)**

3 The AOP presents pertinent information regarding water management for the Missouri
4 River Mainstem Reservoir System. The information in the AOP is based upon water
5 management criteria found in the 2006 Missouri River Master Water Control Manual
6 (Master Manual).

7 The AOP is not a decision document, but rather displays the results of applying the
8 Master Manual criteria over the five runoff conditions: upper decile and quartile, lower
9 decile and quartile, and median runoff. Project releases, reservoir elevations, power
10 production, and other project objectives including endangered species objectives are
11 projected for the runoff scenarios.

12 Other documents related to the AOP provide important context. These include the
13 “System Description”, which describes the system and explains the master manual
14 criteria and project purposes and the “Operation and the Summary of Actual
15 Operations”, which is produced annually and describes the results of the previous year’s
16 operation

17 The draft AOP is produced and distributed in September of each year. Public meetings
18 are held throughout the basin in October. Written comments are taken through the end
19 of November, and the Final AOP is published in December. Public meetings are then
20 held again in April of each year to present the Final AOP. A spring update on current
21 conditions is provided as it relates to AOP implementation. Monthly conference calls are
22 held from January-May (or as needed) to update on current conditions and release
23 plans. These calls are made with interested Federal, state, county and local government
24 representatives, Tribes, levee districts, and media representatives.

25 **2.2.4 Role of decision criteria in the MRRP**

26 The term “decision criteria” refers to the set of pre-determined conditions that trigger or
27 guide a decision or the implementation of a contingency plan. They can be qualitative or
28 quantitative based on the nature of the performance metric and the available
29 information to support a decision, and occur in a variety of forms. A recent study of
30 judicial decisions on AM programs cited the lack of decision criteria as one of three key
31 deficiencies leading to possible overturning by the courts of agency practice (Fischman
32 and Ruhl 2016).

- 1 Decision criteria play several roles in the MRRP; they are designed to:
- 2 • define requirements for compliance purposes (e.g., ESA, NEPA, USACE's policies)
- 3 • ensure that decisions incorporate best available science
- 4 • facilitate complex decisions, or decisions that must be made quickly during
- 5 implementation
- 6 • provide a clear(er) roadmap for participants (i.e., they define the decision space).

7 Decision criteria utilized in the MRRP take various forms, including quantitative

8 triggers (e.g., the criteria for the Lower River Pallid Sturgeon Framework in Section

9 4.2.1.3), decision trees (e.g., diagram addressing drift and dispersal in the Upper

10 Missouri and Yellowstone Rivers in Figure 63), planning rubrics (e.g., the matrix for

11 ESH needs in Table 35), heuristics (e.g., the decisions for flow creation vs. construction

12 in Table 36), and schedules and Gantt charts or flowcharts (e.g., the timeline to

13 implement flow decisions in Figure 28). Even guiding principles, which are evident

14 throughout the AM Plan, can broadly be considered a form of decision criteria.

15 Criteria cannot be developed for every decision faced in executing the MRRP. Some

16 decision criteria may elude development during the initial planning stages; wherever

17 useful criteria simply cannot be developed until details of actions are known. As

18 knowledge grows, it will likely become apparent that some criteria need to be changed.

19 To address these realities, the AM Plan includes a suite of objectives and principles

20 along with a process to guide the development/revision, review, and approval of

21 decision criteria in the future. Attachment 6 of Appendix A provides details on the

22 process to change criteria.

23 **2.2.5 NEPA, the Master Manual, and decisions regarding management actions**

24 The process for adjusting actions, including adding actions not previously implemented

25 or changing the specification of an action, depends on the type, extent, and direction of

26 change needed, and whether the desired action was addressed in the EIS (see Figure 13).

27 If a contemplated action was not evaluated in the EIS, an additional NEPA process (e.g.,

28 supplemental EIS) is required before implementation of the action could occur. If an

29 action was evaluated in the EIS but the analysis was no longer considered adequate

30 (e.g., because of changed environmental concerns or site conditions), additional analysis

31 is likewise be required. If the analysis in the EIS was adequate but the action was not

32 selected in the ROD, new decision documentation would be required before that action

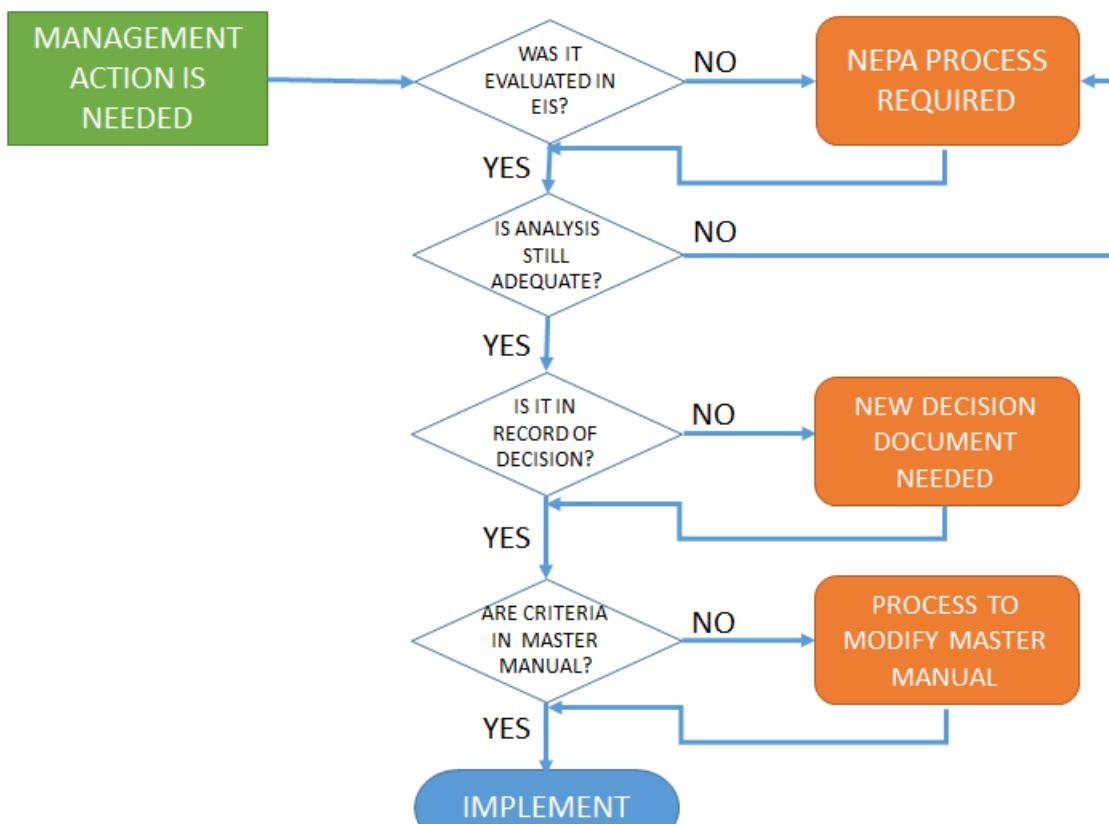

33 can be implemented. Finally, if an action included in the ROD involved flows not

34 consistent with the technical criteria in the Master Manual, modification of the Master

35 Manual would be necessary (see Attachment 5 of Appendix A for details on the

36 procedures for changing the technical criteria in the Master Manual).

3 Figure 13. Flowchart for decisions to implement a management action (Step 5b)¹.

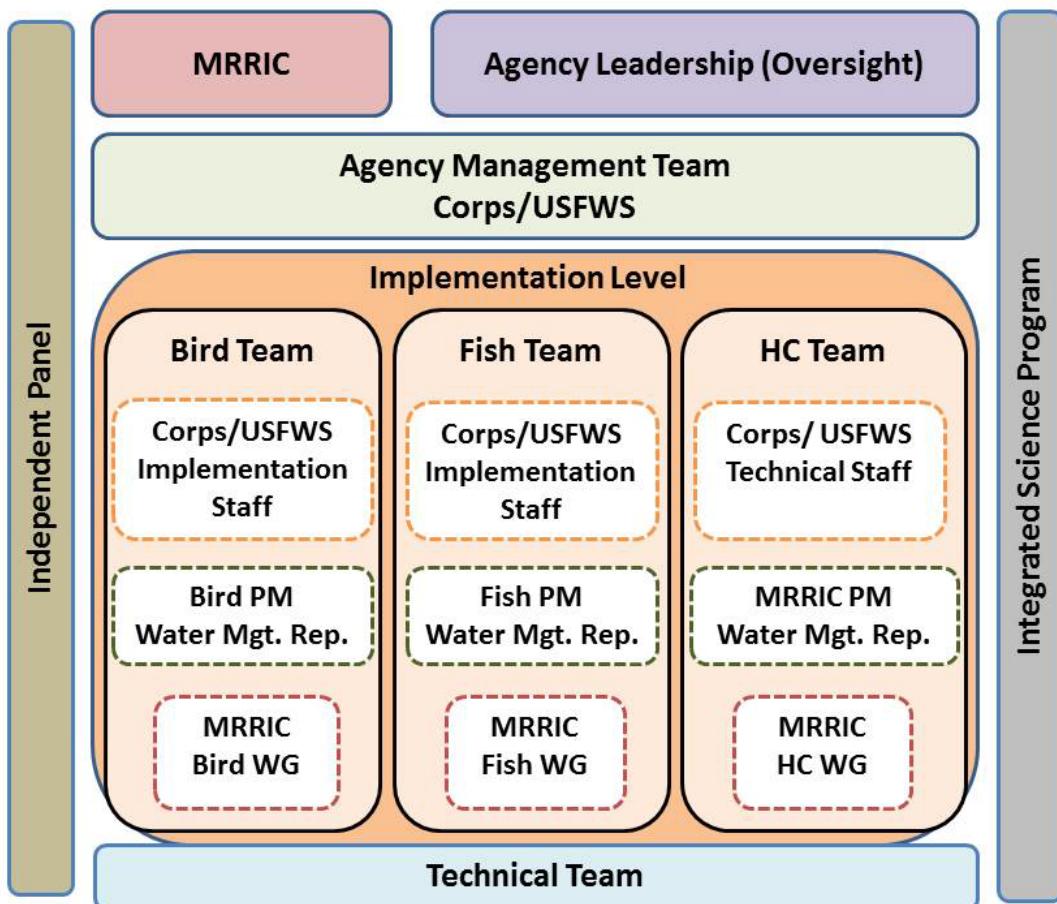

4

5 **2.3 AM program composition, roles, and responsibilities**

6 The MRRP is a collaborative effort amongst the USACE, USFWS, and MRRIC.
 7 Notwithstanding the collaborative nature of the Program, the lead agencies have
 8 statutory responsibilities that cannot be delegated. The role of MRRIC is similarly
 9 defined by relevant legislation (e.g., Sec. 5018 of WRDA, FACA). Descriptions of the
 10 composition, roles and responsibilities for the entities outlined in this section are
 11 intended to (1) comply with the above requirements, (2) maintain transparency and
 12 involve all three entities in the AM learning process and in the formation of
 13 recommendations for actions and research, and (3) achieve the Program's goals and
 14 objectives in the most efficient manner possible.

¹ Note that the last step, involving technical criteria in the Master Manual, would only apply to flow actions.

- 1 Adaptively managing the MRRP is a monumental effort requiring the support of
2 hundreds of individuals from numerous organizations. Not all of those individuals or
3 organizations are represented in this AM Plan. The USACE, in particular, has numerous
4 management and staff positions devoted to supporting the Program that are not
5 reflected in the diagrams, tables, and descriptions in this chapter of the AM Plan.
6 Instead, Chapter 2 focuses on those elements and personnel central to the decision-
7 making process who liaise with and represent the elements of the broader team through
8 engagements among the USACE, USFWS, and MRRIC. Descriptions of the broader
9 team components, which may change over time as the Program emphasis changes, can
10 be found in the Program Management Plan (Attachment 13, Appendix A).
- 11 As described above, the central governance structure consists of several elements
12 generally organized around three levels of authority (Oversight, Management and
13 Implementation), along with technical support and independent review groups in non-
14 decision roles. The composition, roles, and responsibilities of the central elements are
15 summarized in Figure 14 and in Table 10, and are discussed in more detail in the
16 following sections and Attachment 13 of Appendix A. Interaction points and the
17 mechanisms by which these elements function together are described in the AM
18 Decision Process Section (Section 0). To enhance vertical continuity there is overlap
19 between team members throughout this structure.
- 20 Program success demands the commitment of necessary resources to effectively
21 implement and govern the program, commitment on the part of MRRIC and the
22 agencies to engage in a collaborative, transparent process, and the flexibility to change
23 when and where needed. This includes maintaining staffing and contracting capacity to
24 ensure needed expertise is available to the Program, as well as the flexibility to apply
25 available resources to shifting priorities. The actions needed to achieve the Program
26 objectives are uncertain and may evolve, so MRRIC and the agencies must continue
27 their engagement and willingness to work together to identify solutions.

1

2 Figure 14. Central components of the MRRP. Entities not shown in this diagram are referenced in later
 3 sections and described in attachments to Appendix A.

4 Table 10. Summary of roles and responsibilities of entities involved with implementing the MRRP. Not all
 5 entities are represented. See following sections and attachments to Appendix A for additional details.

Entity	Composition	Primary Roles and Responsibilities
Technical Team (Section 2.3.4)	Independent experts, agency staff, and contractors supporting the MRRP in a non-decision, technical role; organized similar to the Effects Analysis Teams	<ul style="list-style-type: none"> Conduct monitoring and assessment of projects Analyze and evaluate data and hypotheses Develop and apply models as needed Interpret results and present findings in reports and at biannual science meetings Assess potential courses of action and outcomes Conduct research and/or undertake focused studies as directed

Entity	Composition	Primary Roles and Responsibilities
Bird and Fish Teams (Section 2.3.3)	Implementation PMs for each species USFWS species representatives AM PM Water Management representative Engineering Division representative Planning Division representative ISP Science Coordinators MRRIC Bird and Fish WGs	<ul style="list-style-type: none"> • Review research, monitoring, and assessment results and make related recommendations • Identify needed research, technical assessments, etc. • Resolve issues related to project siting, construction, operations, etc. • Develop recommendations on prioritizations for management action implementation based on discussions at AM Workshop • Manage contracts, and conduct other “on-the-ground” tasks necessary for implementation
HC Team (Section 2.3.3)	MRRIC PM AM PM USFWS representative Water Management representative USACE technical staff MRRIC HC WG	<ul style="list-style-type: none"> • Review research, monitoring, and assessment results for HC-related concerns • Make recommendations for monitoring, assessment or special studies related to HCs • Identify needed changes in monitoring or assessment protocols
Management Team (Sections 2.3.2, 2.3.6)	Special Assistant – Missouri River Basin Programs (NWD) MRRP Senior PM USFWS MR Coordinator MRRIC PM AM PM Implementation PMs for each species ISP Manager Water Management Representative	<ul style="list-style-type: none"> • Make decisions regarding allocation of budget, staff, and material • Make recommendations on action and research prioritization and flow modifications • Prepare Draft WPs • Recommend changes to program components and governance
Executive Steering Committee (ESC) (Section 2.3.6)	Special Assistant – Missouri River Basin Programs (NWD) Chiefs of Programs and Project Management (NWO and NWK) Chief of CW (NWO and NWK) Chief of Planning (NWO and NWK) Chief of MRBWMD	<ul style="list-style-type: none"> • Review and recommendations on Draft WP • Ensures that the MRRP is implemented according to the direction and guidance provided by the Oversight level • Ensures regional, systems perspective • Resolves district and cross-district disputes • Approves/decides on budget and staffing issues

Entity	Composition	Primary Roles and Responsibilities
Oversight Level (Section 2.3.1)	NWD Commander USACE District Commanders NWD Director of Programs USFWS Region 6 Director USFWS Assistant Regional Director MRRP Senior PM USFWS MR Coordinator Chief of NWD Water Management	<ul style="list-style-type: none"> • Make decisions about priorities • Make decisions regarding flow actions • Make decisions about targets and objectives • Make decisions about program structure and changes • Resolve disputes
MRRIC (Section 2.3.7)	Plenary As defined in Charter	<ul style="list-style-type: none"> • Provides input to AM Plan development and subsequent adjustments to the plan • Make recommendations on WPs • Make recommendations on research needs and priorities • Provide feedback and input on HC assessments/issues of concern
	Bird and Fish WGs (Section 2.3.3)	<ul style="list-style-type: none"> • Works in conjunction with agency staff on Bird/Fish Teams to prioritize the research, project implementation, monitoring, evaluation, and adaptive actions of the MRRP. • Provide information to the full body of MRRIC regarding insights based on science findings, and assist with MRRIC recommendations
	HC WG (Section 2.3.3)	<ul style="list-style-type: none"> • Works in conjunction with agency staff on HC Team to guide recommendations on HC monitoring and assessment priorities • Provide information to the full body of MRRIC regarding insights based on HC effects, and assist with MRRIC recommendations
Independent Advisory Panel	As defined in enabling documentation	<ul style="list-style-type: none"> • Participate in biannual science and AM meetings; review substantive products. • Provide independent scientific and technical advice and recommendations to MRRIC and the lead agencies
Integrated Science Program (Section 2.3.5)	ISP Manager AM PM Terrestrial Science Coordinator Aquatic Sciences Coordinator Support Staff (including partners)	<ul style="list-style-type: none"> • Oversee monitoring and assessment • Oversee research and focused studies • Oversee the Technical Team • Provide program advice to senior leadership and represent the program on science matters
Issue Resolution Board (Section 2.3.6)	NWD Director of Programs USFWS Assistant Regional Director Special Assistant – Missouri River Basin Programs (NWD) USFWS MR Coordinator	<ul style="list-style-type: none"> • Resolves disputes

Entity	Composition	Primary Roles and Responsibilities
Tribes (Section 2.3.6)	As recognized	<ul style="list-style-type: none"> Provide input into the process through communication participation, coordination, and consultation with MRRP
Agencies Outside MRRIC (Section 2.3.6)	State and other Federal agency departments with defined roles outside MRRIC process	<ul style="list-style-type: none"> Regulatory compliance and recommendations on site-specific projects
Public	Refers to individuals acting outside the above categories	<ul style="list-style-type: none"> Provide input to the MRRP in response to any public notice related to the Program

1

2 **2.3.1 Oversight level**

3 Oversight of the MRRP is provided by the USACE Division and District Commanders,
 4 the USFWS Regional Directors and MRRIC. The USACE Commander of the Northwest
 5 Division (NWD) provides Program implementation guidance and direction to the
 6 Omaha and Kansas City District Commanders. The NWD Commander establishes clear
 7 boundaries for the program, makes major policy decisions, and resolves disputes.
 8 Decisions regarding scheduling, staffing, and other resourcing; planning, engineering
 9 and design of management actions; management and execution of the ISP; and other
 10 corresponding activities undertaken at the USACE District offices are overseen by the
 11 Omaha and Kansas City District Commanders.

12 The NWD Commander may elect to delegate decisions to senior leaders within the
 13 command. Decisions regarding the real-time operations of the reservoirs on the
 14 Missouri River are typically delegated to the Chief of the MRBWMD, for example. The
 15 NWD Director of Programs is the NWD Commander's delegate for the day-to-day
 16 oversight of the MRRP. The Director of Programs frequently represents the USACE in
 17 meetings with the MRRIC and/or USFWS and may make decisions related to the
 18 development of the WP, scheduling, resource allocation, and other similar
 19 programmatic issues. The NWD Special Assistant for Missouri River Basin Programs
 20 represents the program in most day-to-day issues.

21 The USFWS Mountain-Prairie (Region 6) Regional Director provides oversight and is
 22 the ultimate guidance and decision-making authority on the MRRP for the USFWS.
 23 Examples of such decisions include the development of or changes to targets and
 24 decision criteria, disposition of hypotheses, introduction of new management actions,
 25 advancement of implementation levels for pallid sturgeon, etc. The Region 6 Regional
 26 Director coordinates and communicates with the Midwest Region (Region 3) Regional
 27 Director. The Regional Director may delegate decisions to subordinate leaders, and
 28 frequently relies upon the Region 6 Assistant Regional Director for Ecological Services

- 1 to represent the agency in meetings with the MRRIC and/or USACE, and to provide
 2 guidance to subordinate teams. The Missouri River Coordinator represents the USFWS
 3 on day-to-day implementation of the MRRP.
- 4 The MRRIC provides guidance and recommendations to the USACE regarding Program
 5 implementation and AM. The roles and responsibilities of the MRRIC are discussed
 6 further in Section 2.3.7. In addition to input from the MRRIC, including consensus
 7 recommendations of the committee, decisions at the Oversight level by the lead agencies
 8 are informed by recommendations from the Management Team. An Executive Steering
 9 Committee (ESC) provides budgeting and resourcing to the Management Team.
 10 Composition of the ESC is discussed in Section 2.3.6.1. Tribal governments, Federal
 11 agencies, and states with statutory authority may be key advisors, as may be other
 12 agency senior support staff. Input from the Independent Panel and the Technical Team
 13 on matters of science also help inform Oversight-level decisions.
- 14 Table 11 provides examples of the decisions and responsibilities at the Oversight level.
 15 The processes and procedures by which the decisions are made are summarized in
 16 Section 0. Some decisions are effectively a joint USACE and USFWS function (e.g.,
 17 changes to targets, decision criteria, or management actions); each agency works within
 18 their authorities to provide decisions that collectively address the broader issue. Their
 19 interaction on these issues with MRRIC is primarily through periodic meetings (see
 20 Section 2.4.2.4). Interactions between senior leadership at the Oversight level and other
 21 agency teams, as well as with MRRIC, are discussed further in Sections 2.3 and 0).

22 **Table 11. Examples of decisions and responsibilities at the Oversight level.**

Decision or Responsibility	Responsible Entity ¹
Make decisions with implications for compliance with the ESA and involving significant change to the AM Plan (e.g., targets, decision criteria, new management actions, etc.).	NWD Commander and USFWS Regional Directors
Approve the Final AM Plan and changes to the plan, including objectives, targets, decision triggers, governance, and decision-making structure	NWD Commander and USFWS Regional Directors
Make decisions on program changes that affect HC	NWD Commander
Make decisions regarding flow operations, including non-routine flows (within ROD and Master Manual but outside of standard operations)	NWD Commander
Approve annual WPs for the MRRP	NWD Commander
Convey consensus recommendations of the MRRIC to the agencies	MRRIC Chairperson

¹ In cases where the decision authority is commonly delegated, the delegate is shown as the responsible entity in this table.

Represent the agencies in interactions with MRRIC, including development and presentation of WPs, etc.	NWD Director of Programs and USFWS Deputy Regional Director
Approve program-level budgetary decisions and resource allocations	NWD Director of Programs
Collaborate with the full MRRIC on human considerations and values-driven trade-off decisions (e.g., channel modifications, flow modifications)	NWD Director of Programs
Coordinate as appropriate with Tribes, federal agencies, state and local government, and the public on site-specific project implementation	District Commanders
Approve District level budgetary decisions and resource allocations at the	District Commanders
Decisions related to constructed project design, implementation, operation and maintenance (O&M), etc.	District Commanders
Make decisions regarding flow operations for the authorized purposes and within existing criteria, or real-time operational decisions	Chief, Water Management
Resolve disputes for subordinate teams	District Commanders (for USACE) or Regional Director (for USFWS)

1 2.3.2 Management Team

- 2 The Management Team is co-led by a USACE NWD Representative (e.g. Special
 3 Assistant for Missouri River Basin Programs) and the USFWS Missouri River
 4 Coordinator, who are responsible for development of the draft WP, resource allocation
 5 and related decisions. The MRRP PM serves as the Alternate Lead. Management Team
 6 membership includes senior PMs for the MRRP from both the USACE and USFWS with
 7 other agency personnel listed in Table 12. Members of the Management Team represent
 8 other entities, as shown in Table 12, and are responsible for communicating activities of
 9 the Management Team with those entities.
- 10 The Management Team develops the Draft WP for presentation draft WP to agency
 11 leadership and the MRRIC based upon the recommendations of the Bird, Fish, and HC
 12 Teams and following guidance provided by the ESC regarding resource availability,
 13 acquisition strategies, etc. The Management Team makes recommendations to senior
 14 leadership on issues requiring Oversight-level decisions. They also provide leadership
 15 for the HC (MRRIC PM), Bird, and Fish Teams (species PMs), and ensure day-to-day
 16 implementation of the MRRP is consistent with requirements in the AM Plan and
 17 direction from senior leadership.

18

19

1

Table 12. Composition of the Management Team.

Member	Role	Represents / Liaison With
USACE		
NWD Representative	Co-Chairperson	NWD Leadership; ESC
Senior PM for MRRP	Alternate Chair	District Leadership; District PMs; District PDTs
MRRIC Project Manager		MRRIC; HC Team
AM Process Manager		Other AM Teams
ISP Manager		ISP; Technical Team
Water Management Representative		MRBWMD
Bird and Fish PMs		Bird and Fish Teams;
OC Representative	Ad hoc	District/Division OC
USFWS		
MR Coordinator	Co-Chairperson	USFWS leadership; FAC Supervisors; ES Project Leads
Bird and Fish Team Leaders		Bird and Fish Teams

2

3 The Management Team is responsible for the allocation of program resources (staff,
 4 budget, and material) with guidance from the ESC and subject to the approval of the
 5 District Commanders (DCs). The DCs will resolve any disputes or conflicts on the
 6 Management Team. The Management Team makes decisions based upon information
 7 provided by the Technical Team, recommendations of the Bird and Fish Teams, and
 8 input from the HC Team, and works closely with the NWD Director of Programs. The
 9 Management Team participates in the annual Fall Science Meeting and the AM
 10 Workshop each spring in advance of the WP preparation. They meet regularly
 11 throughout the year with more extensive engagement when developing the draft WP,
 12 and meet as needed to address other Program considerations.

13 In cases where resource allocation may affect legal compliance (i.e., insufficient
 14 resources are available to meet all objectives), or when the Management Team deems
 15 that changes to the AM Program (objectives, targets, or governance structure and
 16 processes) are warranted or that flow modifications might be required to meet targets,
 17 they make related recommendations to the Oversight level for consideration. The
 18 primary authorities and responsibilities of the Management Team in implementing the
 19 MRRP AM are summarized in Table 13.

20

1 Table 13. Decisions, recommendations and other responsibilities of the Management Team.

Responsibilities	Step in AM Cycle	Category
Decisions¹		
Criteria for implementing habitat construction/modifications	Plan/design	Habitat construction
Criteria for implementing the actions	Plan/design	Plan design
How learning is incorporated into decisions	Plan/design	Plan design
How status and decisions will be reported and communicated	Plan/design	Plan design
What monitoring will be conducted	Plan/design	Plan design
Criteria for implementing population interventions	Plan/design	Population interventions
How much new habitat should be constructed	Adjust/Continue	Habitat construction
Should current habitat be modified	Adjust/Continue	Habitat modification
How resources will be allocated to program components	Adjust/Continue	Program-scale
Whether an active hypothesis should be rejected ²	Adjust/Continue	Research
Whether a reserve hypothesis should be activated ²	Adjust/Continue	Research
Recommendations		
Make recommendations to the Oversight level to adjust objectives, targets, governance structure and processes	Plan/design	Plan design
Make recommendations to the Oversight level when flow modifications are warranted	Adjust/Continue	Flow management
Elevate decisions regarding human considerations (e.g., channel modifications, flow modifications) that require tradeoff analyses to Oversight level for engagement with MRRIC	Adjust/Continue	Program-scale
What additional basic research (demographics, behavior, habitat quality, etc.) is needed. Note: ISP Manager is primary decision maker ²	Adjust/Continue	Research
Whether funding for existing research programs should be continued or resources used elsewhere. ²	Adjust/Continue	Research
Other Responsibilities		
Communicate performance, decisions, and recommendations to the Oversight level, MRRIC, and the Independent Panel, in face-to-face meetings, webinars, and annual and periodic AM reports	Adjust/Continue	Communications
Ensure AM process is implemented throughout the MRRP	Adjust/Continue	Program-scale
Ensure AM process is addressing program needs	Adjust/Continue	Program-scale
Ensure AM recommendations and priorities are reflected in WP	Adjust/Continue	Program-scale

¹ Subject to approval by agency leadership/oversight following MRRIC engagement and deliberation.² Note that the research program is run by the Integrated Science Program (ISP), and the ISP Manager has decision authority over program components. The AM Teams provide input and address resourcing needs.

Responsibilities	Step in AM Cycle	Category
Allocate staff, funding, and other resources for the MRRP within the two agencies, subject to approval of the DCs	Adjust/Continue	Program-scale
Decide based on evaluation results to complete/terminate, adjust, or continue a management action	Adjust/Continue	Habitat construction
Using input from the Implementation Team, develop and finalize WPs, and brief the Oversight level	Adjust/Continue	Program-scale
Approve other recommendations (e.g., revisions to hypotheses, modifications to monitoring efforts)	Adjust/Continue	Plan design
Ensure collaborative process is working and effective	Adjust/Continue	Communications
Engage in the collaborative process at all levels as necessary	Adjust/Continue	Communications
Regularly assess program performance and identify necessary improvements	Adjust/Continue	Program-scale
Responsible for elevating all decisions necessary at Oversight level and ensuring Oversight leadership are provided necessary information to support decision making	All	All

1

2 2.3.3 Implementation-Level Teams

3 The MRRP is implemented by a Bird Team and a Fish Team, each of which includes a
 4 PM, a representative from Water Management, USACE District representatives for
 5 engineering and planning, USFWS Species Team Lead(s) and other appropriate staff
 6 from the lead agencies. A third implementation-level team, the HC Team, addresses
 7 monitoring and assessment needs related to the effects of the Program on HC interests,
 8 and is overseen by the MRRIC Program Manager. Membership and responsibilities of
 9 the Implementation Teams is discussed in the following sections.

10 2.3.3.1 *Bird and Fish Teams*

11 Composition of the Bird and Fish Teams roughly parallel each other, with the
 12 differences consisting primarily in the expertise of individual members. Each team is
 13 chaired by a USACE-appointed PM responsible for implementing the MRRP actions
 14 (typically habitat creation) for the respective species. The AM PM serves as an alternate
 15 to each Chair. Other USACE and USFWS members are as shown in Table 14, and have
 16 responsibilities to represent other entities contributing to the Program to ensure those
 17 needs and perspectives are represented during Team deliberations. Members serve to
 18 liaise with those elements to keep them informed of deliberations and decisions. MRRIC
 19 WG, one for the birds and another for the fish, serve as components of the Bird and
 20 Fish Teams (see Section 2.3.7.2).

21 The Bird and Fish Teams meet at least three times annually, during the Fall Science
 22 Meeting and the AM Workshop to participate in discussions regarding the advancement

1 of scientific understanding, and again in April/May to provide input to the WP. Team
 2 members are expected to interact with the entities they represent before and after each
 3 engagement, and keep the groups they represent apprised of the activities and
 4 decisions/recommendations of the Team. Interactions during the development of the
 5 WP generally involve multiple engagements, including at least one joint meeting of the
 6 Bird, Fish, and HC Teams. Additional details regarding these interactions are provided
 7 in Sections 2.3.6, 2.3.7.2, 2.4.2, and 2.4.3.

8 Table 14. Composition of the Bird and Fish Teams.

Member	Role	Represents / Liaises with
USACE		
Bird/Fish PMs	Chairpersons	Management Team; District PDTs
AM PM	Alternate Chair	Other Implementation Teams; Management Team
ISP Science Coordinators	Member	ISP; Technical Team
Planning Representative	Member	USACE Planning
Engineering Representative	Member	USACE Engineering
Water Management Representative	Member	MRBWMD
OC Representative	Ad hoc Member	District/Division OC
USFWS		
USFWS Fish/Bird Team Leads	Member	Hatchery managers; FAC project leads; Fish Tech Center Lead; Recovery Teams; MRNRC Coordinator; ES Biologists; States (FWCA)
MRRIC Bird/Fish WG		
WG Members	WG Members	MRRIC; Stakeholders

9

10 Members of the species teams are typically responsible for conducting “on-the-ground”
 11 tasks for implementing habitat and population management actions and/or actions and
 12 activities associated with the research and monitoring program, including making
 13 decisions about the way in which many of the actions are carried out. The Teams are
 14 responsible for developing a prioritized list of actions for the Management Team to
 15 consider in developing/updating the MRRP WP. The Bird and Fish Teams must be able
 16 to respond to new knowledge and to changing conditions in the field, to differentiate
 17 between AM and O&M needs, and to implement the guidance in the AM Plan with the
 18 support of decision criteria and contingency plans. They develop their recommendations
 19 based on input from the entities they represent, the Technical Team, and with plans and

1 preliminary designs for candidate projects developed by the District PDTs. Their
 2 responsibilities are summarized in Table 15.

3 Table 15. Decisions, recommendations and other responsibilities of the Bird and Fish Teams.

Responsibilities	Step in AM Cycle	Category
Decisions¹		
Whether adjustments will be made to project design due to unanticipated field conditions	Implement	Habitat construction
Whether population interventions will be made due to unanticipated field conditions	Implement	Population interventions
Where, how much, and how habitat will be constructed	Adjust/Continue	Habitat construction
Whether construction will be implemented experimentally and/or with additional monitoring to increase understanding	Adjust/Continue	Habitat construction
Whether construction methods or design will be changed to improve effectiveness	Adjust/Continue	Habitat construction
What habitat will be modified, and how it is modified	Adjust/Continue	Habitat modification
Whether habitat modification will be implemented with experimental design and/or additional monitoring to increase understanding	Adjust/Continue	Habitat modification
Whether habitat modification methods will be changed to improve effectiveness	Adjust/Continue	Habitat modification
Whether and how much the level of effort and/or protocols of the current monitoring program will be changed	Adjust/Continue	Monitoring
Whether additional monitoring will be conducted in the long term (current metrics are insufficient)	Adjust/Continue	Monitoring
Whether additional monitoring will be conducted in the short- or moderate-term because of unusual conditions or natural events	Adjust/Continue	Monitoring
What additional monitoring and/or research will accompany a non-routine flow action	Adjust/Continue	Non-routine flow modification
Whether and where population interventions will be implemented	Adjust/Continue	Population interventions
Recommendations		
Whether flows should be implemented in a way to increase understanding	Adjust/Continue	Non-routine flow modification
Additional ways to improve the effectiveness of non-routine flow actions within the current constraints	Adjust/Continue	Non-routine flow modification
Whether routine flow management should be changed during implementation because of HC or species impacts	Implement	Routine flow management

¹ Subject to approval by appropriate agency leadership and following other policies and practices laid out by the agencies and/or described in the AMP.

Responsibilities	Step in AM Cycle	Category
Whether non-routine flows should be changed or terminated during implementation	Implement	Non-routine flow modification
Whether population interventions should be implemented with experimental design and/or additional monitoring to increase understanding	Adjust/Continue	Population interventions
Whether population interventions methods should be changed to improve effectiveness	Adjust/Continue	Population interventions
Whether flows should be managed during the nesting season to reduce incidental take (inundation of nests or chicks)	Adjust/Continue	Routine flow management
Whether flows should be implemented in a way to increase understanding	Adjust/Continue	Routine flow management
Additional ways to improve the effectiveness of routine flow management within the current constraints	Adjust/Continue	Routine flow management
Whether flow management could be adjusted (magnitude, duration, timing) to reduce impacts or increase effectiveness	Adjust/Continue	Routine flow management
Develop input to Annual Operating Plans for water management	Adjust/Continue	Program level
Other Responsibilities		
Determine costs of habitat projects, population intervention actions, research and monitoring	Adjust/Continue	Program level
Manage contracts for implementing project work	Adjust/Continue	Program level
Decide where to implement habitat and population management actions (site-level)	Adjust/Continue	Habitat construction
Design habitat and population management actions	Adjust/Continue	Habitat construction
Design and conduct research and monitoring programs or related contracted work	Adjust/Continue	Research
Respond to changing field conditions to adjust implementation as necessary	Adjust/Continue	Program level
Provide after-action assessment of project work to the Technical and Management Teams	Adjust/Continue	Program level

1

2 2.3.3.2 *Human Considerations (HC) Team*

- 3 The HC Team is chaired by the USACE MRRIC PM, who is responsible for convening
 4 the team, keeping members informed of relevant issues and activities, and representing
 5 the HC Team as a member of the Management Team (see Table 16). The Tribal Lead
 6 serves as an alternate Chair. Other USACE and USFWS members are assigned as
 7 needed, and are generally technical specialists representing specific interests of the team
 8 at that time. Members serve to liaise with those elements to keep them informed of
 9 deliberations and decisions. An MRRIC HC WG also serves as a member of the team.
 10 See Section 2.3.7.2 for more details about the role and composition of the HC WG.

1 Table 16. Composition of the HC Team.

Member	Role	Represents / Liaison With
USACE		
MRRIC PM	Chairperson	Management Team; other AM Teams; USACE leadership
Tribal Lead	Alternate Chair	Tribes
USACE Technical Specialists		USACE Planning; ISP
Water Management Representative		MRBWMD
OC Representative	Ad hoc Member	District/Division OC
USFWS		
USFWS Representative		USFWS leadership
HC WG		
WG Members		MRRIC; Stakeholders

2

3 The HC Team meets at least three times annually, during the Fall Science Meeting and
 4 the AM Workshop to participate in discussions regarding the advancement of scientific
 5 understanding, and again in April/May to provide input to the WP. Team members are
 6 expected to interact with the entities they represent before and after each engagement,
 7 and keep the groups they represent apprised of the activities and
 8 decisions/recommendations of the Team. Interactions during the development of the
 9 WP may involve multiple engagements, including at least one joint meeting of the Bird,
 10 Fish and HC Teams. Additional details regarding these interactions are provided in
 11 Sections 2.3.6, 2.3.7.2, 2.4.2, and 2.4.3.

12 The HC Team provides input to the MRRP monitoring and assessment program, as it
 13 pertains to HCs and the effects of Program decisions on conditions of interest to
 14 stakeholders (Table 17). The Team is responsible for developing a prioritized list of
 15 monitoring and assessment needs for the Management Team to consider in
 16 developing/updating the MRRP WP. The Team must be able to respond to new
 17 knowledge and to changing conditions in the field, to evaluate monitoring and
 18 assessment results provided by the Technical Team, to assess protocols for monitoring
 19 and assessment, and to follow the guidance in the AM Plan or recommended changes to
 20 the guidance in the event objectives are not being met. Their responsibilities are
 21 summarized in Table 17.

22

1 Table 17. Recommendations and other responsibilities of the HC Team.

Responsibilities	Step in AM Cycle	Category
Recommendations		
Whether and how protocols of the current monitoring program will be changed	Adjust/Continue	Monitoring
Whether additional monitoring should be conducted beyond the existing program in the long term (current metrics are insufficient)	Adjust/Continue	Monitoring
Whether additional monitoring should be conducted in the short- or moderate-term because of unusual conditions or natural events	Adjust/Continue	Monitoring
Whether ongoing monitoring or studies should be terminated based on changed needs or new information	Adjust/Continue	Monitoring
What additional monitoring and/or research will accompany a non-routine or test flow	Adjust/Continue	Non-routine flow modification
Other Responsibilities		
Identify needs for research or special studies related to HCs	Adjust/Continue	Research
Provide after-action evaluations of existing monitoring and assessment to the Technical and Management Teams.	Adjust/Continue	Program level
Inform MRRIC of activities and provide input on possible Recommendations, as warranted (HC WG only)	Adjust/Continue	Program level

2

3 2.3.4 Technical Team

4 A Technical Team, patterned after the EA, is responsible for developing and compiling
 5 the information used by the other teams and by the Oversight level to make decisions
 6 regarding the MRRP (Table 18). The Technical Team is not a decision-making body, but
 7 provides information and analysis based on research and evaluation results to the
 8 agencies and MRRIC. The Technical Team uses information from research and
 9 monitoring to develop and provide reports and assessments that all teams use in
 10 decision making. The reports and assessments capture and update the knowledge of the
 11 habitat and population status, hypotheses including action effectiveness of previously
 12 implemented actions on the habitat and species, and conceptual and predictive models.
 13 They use the information about System status, assess how AM Plan decision criteria are
 14 being addressed together with other criteria and information to evaluate a range of
 15 management options, and use predictive numerical models to the fullest extent possible.
 16 They provide expertise in AM and perform assessments of Program performance and
 17 make suggestions for improvements. They engage with the ISAP/ISETR for discussions
 18 supporting independent review of annual reports or other studies. In addition to any
 19 specific study reports assigned to the team, they provide a draft annual AM report in

- 1 advance of the AM Workshop and a final annual AM report following receipt review
 2 comments and input from the Science Update process.
- 3 The Technical Team includes subject matter experts in ecology, biostatistics,
 4 hydrodynamics, fluvial processes, decision analysis, river operations, spatial statistics
 5 and socio-economics, and include individuals with expertise and experience in
 6 assimilation and analysis of information related to plovers, pallid sturgeon, and the
 7 hydrogeomorphology of the Missouri River. Composition of the Technical Team may
 8 include Federal and state agency personnel, university professors, and contractors
 9 selected to address the underpinning science for the program. The Technical Team
 10 works closely with the ISP Manager and is overseen by the AM Process Manager, who
 11 are also members of the Bird/Fish and Management Teams and may convey results and
 12 recommendations from the Technical Team to those teams.
- 13 Technical Team members will likely not be co-located, so they should be given
 14 opportunities to meet as needed to execute their responsibilities. They conduct their
 15 assignments using best available commercial or public data, and contribute to
 16 assessments of these data. At all times, they seek to operate in a transparent, objective
 17 manner using accepted standards of professional practice. At a minimum, they
 18 participate in the Fall Science Meeting and the AM Workshop, and are represented at
 19 any meeting of the Management, HC, Bird, and/or Fish Team, as requested by those
 20 teams. Responsibilities include, but may not be limited to the items listed in Table 18.

21 Table 18. Responsibilities of the Technical Team.

Responsibilities	Step in AM Cycle	Category
Recommend and organize sub-groups with specific expertise, as needed	Plan/Design	Program
Develop experimental design for management actions	Plan/Design	Program
Make recommendations on information management, including data systems, publications, etc.	Plan/Design	Program
Make recommendations about monitoring and research to the Management and Implementation Teams	Plan/Design	Monitoring and Research
Evaluate, test and update numerical and conceptual ecological models (CEMs)	Evaluate	Program
Test and evaluate hypotheses and make recommendations on hypothesis priorities	Evaluate	Program
Update, revise, and prioritize assessments of critical uncertainties	Evaluate	Program

Responsibilities	Step in AM Cycle	Category
Simulate the outcomes of management actions using quantitative models	Evaluate	Program
Provide evaluations and recommendations to the Bird and Fish Teams and the Management Team as needed	Evaluate	Program
Engage with MRRIC, the Independent Panel, and MRRIC WGs as part of the Science Update process	Evaluate	Program
Undertake special studies or conduct research as directed	Evaluate	Research
Recommend ad hoc peer review panels to conduct independent scientific review	Evaluate	Program
Translate new scientific information into the technical component of AM reports	Evaluate	Program
Synthesize and evaluate data to compare monitoring and research results to decision triggers and targets	Evaluate	Monitoring

1

2 **2.3.5 Integrated Science Program (ISP)**

3 The ISP is the component of the MRRP responsible for overseeing and conducting
 4 scientific monitoring and investigations to assist the USACE in avoidance of jeopardy
 5 and compliance with the BiOp. The ISP monitors federally-listed species under the
 6 Endangered Species Act (ESA), the habitats upon which they depend, and conducts
 7 research and monitoring to address key uncertainties in support of AM. The ISP
 8 coordinates science activities in a collaborative manner among USACE, state and
 9 Federal partners.

10 The purpose of the ISP includes the following:

- 11 1. Implementation of system-wide monitoring activities and focused investigations to
 12 address BiOp mandates and jeopardy avoidance for the federally- listed species.
- 13 2. Evaluation of MRRP actions on the federally- listed species.
- 14 3. Provision of scientific and technical support for MRRP efforts, implementation,
 15 design & construction, Operation & Maintenance (O&M), and the AM process; and.
- 16 4. Communication of Missouri River Basin science to stakeholders including Federal,
 17 state, local agencies, tribal governments, and MRRIC.

18 Although Corps District staffed and supervised, the ISP is a trans-District organization
 19 and works closely with leadership for both Districts and the NWD in support of the
 20 Program objectives. The ISP Manager oversees the day-to-day ISP execution and is a
 21 member of the Management Team. The ISP is organized into two disciplines: (1)

1 Terrestrial Science; and (2) Aquatic Science. Senior scientists serve as coordinators for
2 these components of the ISP, report to the ISP Manager, and are members of the Bird
3 and Fish Teams, respectively. The ISP Manager and coordinators are supported by
4 technical staff, a program analyst, and an administrative assistant. Details regarding the
5 composition and roles of the ISP are provided in the ISP Program Management Plan (see
6 Attachment 14 of Appendix A). Details on the requirements and procedures of the ISP
7 are presented in Appendix J.

8 The ISP implements the focused investigations and research activities of the MRRP and
9 sets the standards and requirements for related activities. The ISP ensures appropriate
10 monitoring, assessment, and research activities are implemented in a timely manner to
11 track progress towards meeting program objectives, reducing uncertainties, and
12 identifying needed program adjustments. The ISP provides contract and staffing
13 support to all science activities and ensures that research and monitoring meet Program
14 standards, and are properly coordinated, collaborative and efficient.

15 The ISP Manager is responsible for communicating findings in an objective and
16 transparent way to the agencies, MRRIC and Missouri River Basin stakeholders through
17 various reporting mechanisms, such as the annual report, periodic reports, update
18 presentations, and a variety of other reports (see Chapter 6). The ISP Manager is also
19 responsible for planning and conducting the Annual AM Workshop, during which major
20 findings, research results, etc., are reported and upcoming monitoring and research
21 activities discussed (see Section 2.4.3.2).

22 Details on the requirements and procedures of the ISP are presented in Appendix J.
23 Other decisions and responsibilities within the domain of the ISP include, but are not
24 limited to the following:

- 25 • implementation of the Program's monitoring and assessment program,
- 26 • compilation of the scientific information necessary to identify and address the
27 uncertainties associated with jeopardy avoidance and BiOp compliance,
- 28 • communicating Missouri River Basin science to agency leadership, MRRIC and
29 stakeholders,
- 30 • contracting and managing research and monitoring for the Program,
- 31 • coordinating MRRP science activities among and across agencies,
- 32 • developing and maintaining a data management and reporting system,
- 33 • obtaining needed technical expertise through agency staffing and the Technical
34 Team,
- 35 • implementing periodic external peer reviews of Program components, and
- 36 • coordinating the Fall Science Meeting and AM Workshop.

1 **2.3.6 Other MRRP entities and position descriptions**

2 *2.3.6.1 Executive Steering Committee (ESC)*

3 The ESC ensures that the MRRP is implemented according to the direction and
4 guidance provided at the Oversight level and that the WP reflects a regional, systems
5 approach to achieving its objectives and is consistent with budget, acquisition, and other
6 constraints. They ensure appropriate staffing and the effective use of district resources,
7 considering the needs of the MRRP, other water resources projects on the Missouri
8 River, and other Civil Works demands in the basin. The ESC meets quarterly or more
9 frequently as issues require. Specifically, the ESC has the following responsibilities:

- 10 1. Provide guidance and direction to the Management Team on implementation of the
11 program to achieve program overarching goals and objectives and for intra- and
12 inter-annual variations in program execution based on conditions in the basin.
- 13 2. Resolve inter-district/interagency conflicts in support of regional operation.
- 14 3. Act as liaison with senior leadership at the district and division.
- 15 4. Provide review and approval for MRRP WP budgets prepared by the Management
16 Team.
- 17 5. Direct and manage the following:
 - 18 a. Staffing, organization, and manning needs
 - 19 b. Other resources needed to support the MRRP
 - 20 c. Workload balancing between districts to maintain technical capability
 - 21 d. Acquisition strategy for MRRP activities.

22 The ESC is composed of the following members:

- 23 • NWD Representative (e.g. Special Assistant – Missouri River Basin Programs or
24 Chief of Planning, Environmental Resources, Fish Policy, and Support)
- 25 • Chiefs of Programs and Project Management (NWO and NWK)
- 26 • Chief of the Missouri River Basin Water Management Division (NWD)

27
28 Ad hoc members of the ESC include the following¹:

- 29 • Chiefs of CW (NWO and NWK)
- 30 • Chiefs of Planning (NWO and NWK)
- 31 • MRRP Senior PM

¹ The role of the ad hoc membership is to provide continuity between the Management Team and the ESC

- 1 2.3.6.2 NWD Representative (e.g. Special Assistant – Missouri River Basin Programs)
- 2 The NWD Representative is responsible for management, oversight, and coordination of
3 NWD perspectives for program activities related to the MRRP (including the AM
4 Plan/MRRPMP-EIS). The NWD Representative chairs the ESC, is a member of the Issue
5 Resolution Group, and serves as a liaison between the Management Team, other District
6 MRRP AM Teams, and the NWD Director of Programs. The NWD Representative works
7 closely with the PMs to ensure consistent messaging/communication strategies and
8 maintains a collaborative working relationship with Missouri River Basin Water
9 Management, ensuring full integration of water management considerations into
10 Missouri River Programs. The NWD Representative provides support to the Programs
11 Director and/or Planning Chief or represents those entities on boards and committees
12 as authorized, including the MRRP ESC, Missouri River Recovery Implementation
13 Committee (MRRRIC), Missouri River Association of States and Tribes (MORAST),
14 Missouri River Basin Interagency Roundtable (MRBIR), Tribal interactions, and at
15 public meetings.
- 16 2.3.6.3 Senior Program Manager (SPM) for MRRP)
- 17 The role of the SPM is to ensure implementation of the MRRP is consistent with USACE
18 policy, to communicate the MRRP strategic vision, goals, relevant guidance from senior
19 Leadership to all internal and external MRRP teams and stakeholders. The SPM assists
20 the Bird Federal agencies, states, and tribes, and works to ensure that these
21 relationships are maintained. The MRRP SPM serves as the Management Team lead,
22 and coordinates efforts among other Teams to ensure that actions and communication
23 are consistent with programmatic goals. The SPM develops and assigns budgets and
24 tasks for communications, outreach, and tribal consultation, and works with the ESC to
25 ensure the Program is properly resourced to meet its objectives. Specific tasks of the
26 SPM may include the following:
- 27 • Development and updating of three-year budget requests and a five-year strategic
28 program plan through full coordination with, and input from, other agency Teams,
29 MRRIC, and senior leadership (Oversight)
30 • Coordination with the Bird, Fish, and HC Teams and the ESC on the development of
31 a MRRP WP and budget. This WP and budget are integrated among the districts
32 with a goal to achieve 95% or better of annually scheduled program obligations. The
33 SPM coordinates and oversees the preparation of a programmatic WP by the
34 Management Team, based on prioritized recommendations of the species teams and
35 considering input from the MRRIC HC WG and Tribes

- 1 • Development, facilitation, and implementation of a Tribal Engagement Strategy with
2 tribes in the Missouri River Basin through close coordination with the MRRP Tribal
3 Lead and district tribal liaisons
- 4 • Coordination of all MRRP outreach, communication, and collaboration including
5 support to MRRIC
- 6 • Implementation and maintenance of data management and communications
7 systems/programs, including automated reporting, development, and distribution of
8 annual reports, fact sheets, and other MRRP-funded reports
- 9 • Attendance and reporting at Project Review Committee (PRC), Project Review Board
10 (PRBC), and Mitigation Agency Coordination Team (Mitigation ACT) meetings, as
11 appropriate and needed by each district.

12 The SPM is ultimately responsible for critical outputs from the MRRP Program, and will
13 track progress toward milestones for all Program products. The SPM will issue tasks to
14 subordinate team members outlining the products for which they are responsible, and
15 ensure they are implemented efficiently and effectively (i.e., cost and quality).

16 2.3.6.4 *Missouri River Recovery Implementation Committee Project Manager (MRRIC PM)*

17 The MRRIC PM implements the MRRIC with Federal, tribal, and state partners and
18 stakeholders using an AM approach. The MRRIC PM is a member of the Management
19 Team and coordinates MRRIC-related processes and activities within the USACE,
20 including the vertical team and with the Federal Working Group (FWG).
21 Responsibilities of the MRRIC PM are: (1) plan, support, and manage interactions
22 between the USACE and MRRIC; (2) coordinate input from MRRIC to the MRRP AMP;
23 and (3) plan and manage the MRRIC budget and schedule.

24 2.3.6.5 *Missouri River Adaptive Management Process Manager (AM PM)*

25 The AM PM is responsible for coordinating the AM program and works closely with the
26 SPM, ISP, and the AM Teams to ensure AM principles and practices are incorporated
27 into all phases of MRRP implementation. While the ISP PM provides scientific
28 monitoring and research results for the Threatened and Endangered (T&E) species and
29 their respective habitats addressed under the BiOp, the AM PM is responsible for
30 ensuring this information is easily accessible to and understood by members of the AM
31 Teams, other agencies, states, tribes, stakeholder groups, and the public. The AM PM is
32 a member of the Management Team, and an ad hoc member of the Bird, Fish, and HC
33 Teams. Other responsibilities include (1) providing AM expertise for the Program, (2)
34 AM coordination amongst the ISP, AM Teams, and MRRIC, and (3) the preparation and
35 distribution of AM reports.

1 2.3.6.6 *Tribal Lead*

2 The Tribal Lead is a member of the HC Team and is responsible for coordinating/
3 communicating MRRP developments with the 28 tribal nations located in the Missouri
4 River Basin, in addition to any tribe that claims a historical tie and/or holds land within
5 the basin. Much of this coordination is accomplished through the MRRIC; however, the
6 tribal lead coordinates directly with each tribe and ensures that their councils are aware
7 of proposed budgets and activities for each FY. A key responsibility is to communicate
8 concerns expressed by individual tribal nations about specific actions or projects to
9 MRRP management for consideration. The tribal lead coordinates resolution of these
10 issues, recognizing not all requests can be accommodated, and provides feedback to the
11 tribe making the request. If a project should result from the consultation process, the
12 tribal lead serves as PM. For those tribes unable to have representation at each MRRIC
13 meeting, the tribal lead is to ensure tribal governments receive information discussed at
14 these important stakeholder meetings and that they are aware of pending decision-
15 making opportunities. The Tribal Lead coordinates activities with the tribal liaisons of
16 both the NWO and NWK districts.

17 2.3.6.7 *Missouri River Basin Water Management Representative (WM Representative)*

18 The WM Representative serves as the interface between the MRRP and the NWD
19 MRBWMD. A WM Representative (there can be multiple and alternate representatives)
20 is a member of each of the Implementation Teams and the Management Team. The WM
21 Representative is responsible for reporting any issues addressing water management
22 decisions and their potential impact on the program. The WM Representative makes
23 recommendations to the teams on strategies to avoid or minimize take, provides
24 information on water management forecasting (effects of the AOP for the Missouri
25 River, and provides technical insights into team discussions regarding potential flow
26 management actions.

27 2.3.6.8 *Office of Counsel (OC)*

28 Representatives of the Office of Counsel (OC) for NWD and for the District OC (both
29 NWK and NWO) provide guidance and advice on all legal matters related to
30 administration and implementation of the program. The OC representatives collaborate
31 to address intra-district and inter-district MRRP-related issues. Attorney assignments
32 on inter-district regional activities in the Missouri River Basin are not intended to
33 change existing relationships for intra-district activities and their district OCs, nor for
34 NWD Water Management staff and NWD OC.

1 Attorneys from OC also work closely with the Implementation (Bird and Fish) and
2 Management Teams, the ESC and MRRIC. Attorneys are regular participants in Team
3 meetings as well as on-call advisors. There may well be both NWD and district
4 attorneys involved in these activities at any given time. Information sharing among the
5 attorneys is important for successful, integrated Missouri River programs. Specific real
6 estate, contracting and regulatory activities will generally be served by an attorney from
7 the OC in the District where the action officer is assigned.

8 **2.3.6.9 Issue Resolution Board**

9 The Issue Resolution Board is a group that considers disputes between Program entities,
10 agencies, or between an agency and MRRIC. The Issue Resolution Board consists of the
11 NWD Director of Programs and the NWD MRRP Representative, as well as Region 6
12 Assistant Director and the Missouri River Coordinator for the USFWS. Every effort
13 should be exhausted before seeking resolution through the Board, and any request for
14 issue resolution should follow the procedures outlined in Section 2.5.1. If the Issue
15 Resolution Board cannot resolve the issue and it cannot be resolved through the normal
16 engagement process, it will be elevated to the NWD Commander for a decision.

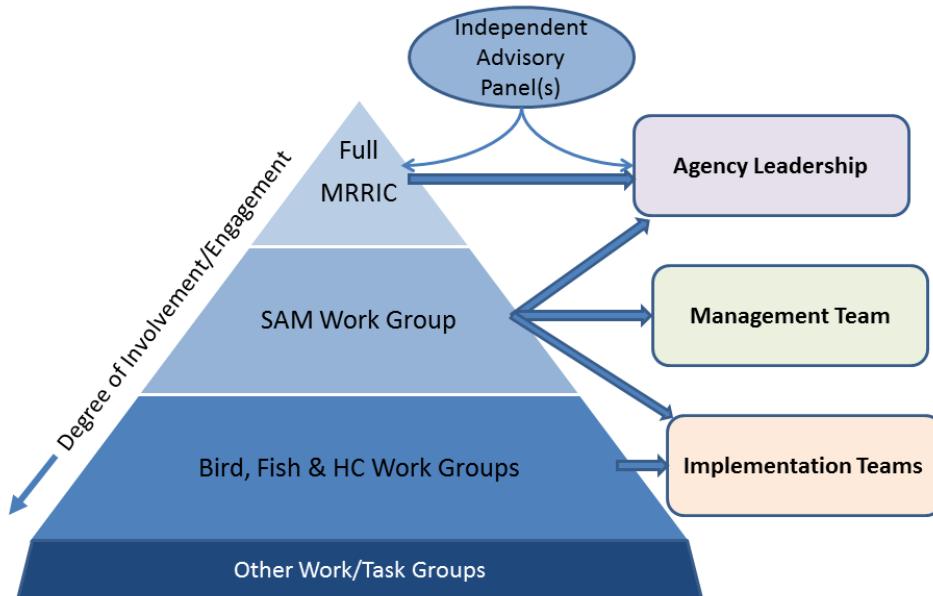

17 **2.3.7 Overview of MRRIC roles and responsibilities**

18 The Missouri River Recovery Implementation Committee (MRRIC) represents
19 stakeholder interests for the MRRP. As described in WRDA Section 5018 (3) (B) (i)),
20 “The Committee (MRRIC) shall provide guidance to the Secretary with respect to the
21 Missouri River recovery and mitigation plan in existence on the date of enactment of
22 this Act, including recommendations relating to changes to the implementation strategy
23 from the use of adaptive management.” The AM engagement approach laid out in this
24 AM Plan should be considered the vehicle for the MRRIC, in collaboration with the
25 USACE, to achieve this objective. In addition, the Charter for the MRRIC includes, as
26 part of the Committee’s purpose and scope [1] a) iii]: “Provide recommendations and
27 guidance that will include:

- 28 1. Recognition of local stakeholders' social and economic, historical and cultural, flood
29 control, irrigation, agriculture, internal drainage, water supply, water quality,
30 navigation, hydropower, thermal power, science, natural resources, conservation,
31 and recreation issues, and any other issues identified by the Committee
- 32 2. Identification of impacts to stakeholders
- 33 3. Identification of actions that will benefit multiple uses of the river (MRRIC 2014).”

34 In executing this role, the MRRIC and the agencies each bear responsibilities for
35 Program execution and for effective collaboration and decision making. Adherence to

- 1 basic principles already outlined and reiterated below will help ensure this occurs. As a
 2 practical matter, the MRRIC will continue to rely on WGs, Task Groups, and the
 3 Independent Advisory Panel to engage at the necessary level of detail with elements of
 4 the agencies and the AM Program and provide the full body of the MRRIC with insights
 5 and recommendations (Figure 15). The MRRIC relies upon WGs to collaborate on issues
 6 through frequent interactions with agency specialists, and provides input to the agencies
 7 and the full MRRIC based on those interactions. The full MRRIC weighs in on the most
 8 significant issues based upon WG input, and focuses on WP recommendations.
- 9 Figure 15 provides an overview of the roles for MRRIC and its key WGs. The schematic
 10 shows that the MRRIC would rely upon three WGs to collaborate on issues through
 11 frequent interactions with agency specialists and provide input to the agencies and the
 12 full Committee based on those interactions. The full Committee would weigh in on the
 13 most significant issues based upon the WG input, as well as focus on recommendations
 14 for the WP. More details are given in the following sections, elsewhere in the AM Plan,
 15 and its appendices and attachments.

16

17 Figure 15. Schematic of MRRIC roles in implementing the MRRP AM Plan.

18 2.3.7.1 MRRP collaborative forum composition, roles, and responsibilities.

19 The MRRIC Charter (MRRIC 2014 [amended from 2009]) and Operating Procedures
 20 and Ground Rules (MRRIC 2016 [amended from 2009]) establish the objectives for
 21 MRRIC and its mechanisms for achieving those objectives (see Attachments 1 and 2 of
 22 Appendix A). The MRRIC plenary meetings provide the primary forum for collaborative

1 engagement where a consensus recommendation is needed or desired. Other
2 opportunities for collaboration and input to the MRRP are described in later sections of
3 this chapter (see Section 2.3.7.2 through 2.3.7.4 and Section 0).

4 MRRIC advanced and approved an engagement strategy for the development and
5 implementation of an AM Plan for the MRRP (MRRIC 2011). That document outlines a
6 set of principles that remain relevant to the current and future efforts under the MRRP
7 (MRRIC 2011, see Sections 2.3 and 2.4.5). In addition, the agencies have engaged with
8 the AM ad hoc WG to develop a collaborative governance process. Those engagements
9 produced useful input to the process and a draft recommendation to the MRRIC that
10 resulted in a consensus recommendation on governance. The following sections draw
11 from that effort in describing a set of WGs that interact with the agency teams and the
12 process for implementing AM to influence the WP.

13 **2.3.7.2 MRRIC Bird, Fish, and HC WGs**

14 Developing and implementing AM strategies requires interactive and timely
15 deliberations. MRRIC established the Science and Adaptive Management (SAM) WG to
16 guide MRRIC recommendations to prioritize the implementation, monitoring,
17 evaluation, and adaptation actions of the MRRP. The SAM also reviews and provides
18 draft recommendations related to the MRRP's WP for MRRIC's consideration. Three
19 permanent WGs (Bird, Fish, and HC) support the MRRIC and function at the
20 implementation level to inform the program as it moves into an implementation phase.

21 The Bird, Fish, and HC WGs engage with and are part of the Bird, Fish, and HC Teams,
22 respectively (see Figure 14). Each Team includes lead agency staff involved in
23 implementation of the MRRP and its AM Plan. A core group of agency staff on each
24 team works on the Program full time while others engage as needed and at key points of
25 the process or when meetings occur. Members of the team not engaged fulltime in the
26 effort – including MRRIC members on the WGs and supporting agency staff – receive
27 regular information updates and meet at defined times throughout the year.

28 The main role of the Bird and Fish WGs is to understand the science and technical
29 issues that relate to the piping plover and pallid sturgeon and underpin the Program.
30 This includes understanding what actions are being implemented for the birds/fish, the
31 status of hypotheses related to the birds/fish, and how the models work and the
32 implications of updated model results. The WGs are responsible for providing
33 comments/feedback to the lead agencies (during meetings with Bird, Fish, and HC
34 Teams and through WG reports), keeping the full MRRIC informed of their
35 comments/feedback, and bringing forth issues to MRRIC that may need a formal
36 recommendation from the full committee. A fundamental product of each Team is the

- 1 development of a prioritized set of actions for each species annually to help the
2 Management Team with development of WP updates. WGs contribute to those products
3 and provide related feedback to the MRRIC.
- 4 The composition of the HC WG and the HC Team are similar to those for the birds and
5 fish. However, the role of the HC Work Team is to understand the technical aspects of
6 AM that relate to human uses of the Missouri River System. This includes
7 understanding how HC's are being accounted for in AM and understanding the
8 hydrologic, hydraulic, economic, or other models used to predict effects to HCs. HC
9 Team's recommendations center on monitoring and assessment of the effects of MRRP
10 actions on HC interests. The Team does not provide input to the prioritization of
11 management actions; that is a function of the full MRRIC. The main responsibilities of
12 the HC WG include providing comments/feedback to the Federal agencies (during
13 meetings with the HC Team and possibly during real-time operations), keeping the full
14 MRRIC informed of their comments/feedback, working with the full MRRIC to assess
15 the adequacy of the human consideration monitoring metrics, and bringing forth issues
16 to MRRIC that may need a formal recommendation from the full committee.
- 17 While many MRRIC members are likely to have an interest in participating on these
18 WGs, they should have reasonable expectations regarding the level of effort and nature
19 of the work before committing to serve as a WG member. However, members must be
20 able to commit the time and energy to stay involved, understand the issues, and stay
21 meaningfully engaged in the technical discussions regarding application of science to
22 species needs. Reasonable expectations regarding the level of effort are therefore
23 essential before committing to serve as a WG member. WG members should expect to
24 devote up to a month of their time annually in order to effectively engage with the
25 Teams, stay abreast of developments, prepare reports, and maintain sufficient
26 participation.
- 27 WG interactions with the teams are coordinated by the Implementation PM for each
28 species team and the MRRIC PM for the HC Team. An MRRIC Representative serves as
29 a point-of-contact for each WG. These interactions are assisted by a third-party
30 facilitator initially and until such time as the MRRIC and agencies agree facilitation is
31 no longer required. These three positions constitute the core of a 'planning group' that
32 identifies and confirms dates for meetings and calls, develops draft agendas for work
33 Team/WG review and considerations, and assists in other administrative preparations
34 as necessary. The WG meetings with the teams will be facilitated, recorded, and
35 summarized by the third-party facilitator. The recording and summary is shared with
36 WG members as well as other interested parties including, but not limited to, the full
37 MRRIC.

1 The WG Representative and agency lead PM for each Team are responsible for keeping
2 WG members apprised of activities of the Team. The full WG is expected to meet with
3 the rest of the Team as often as necessary to accomplish the tasks assigned to the team,
4 but at a minimum, three times each year as follows:

- 5 • In October/November – at the Fall Science Meeting – to obtain briefings on the
6 status of monitoring activities, early performance observations, research in-
7 progress reviews, and other noteworthy activities of the team; and to provide
8 input into the activities of the team for the following quarter.
- 9 • In February – at the Annual AM Workshop – to participate in discussions of
10 significant science findings, performance of past management action
11 implementations, prioritization of research needs and project implementation
12 proposals, and recommendations for the WP.
- 13 • And in April/May – after the release of the agencies' draft WP – to review
14 proposed project implementation plans, monitoring plans, and other program
15 activities and discuss any significant adjustments to plans due to budget changes.

16 Each WG contributes to a collective report annually, following the annual AM
17 Workshop, capturing the range of conversations and ideas associated with the area of
18 focus and providing recommendations and priorities for needed research, project
19 implementation, monitoring and assessment activities, etc. The reports from the three
20 teams are integrated and provided to the Management Team for consideration, and will
21 constitute the basis for draft changes to the WP by the Management Team. The WGs
22 have the opportunity to share their observations including the range of their
23 perspectives, provide individual or consolidated reports, and draft recommendations,
24 directly with MRRIC in preparation for potential recommendations to the agencies.

25 To effectively involve MRRIC in the AM program, it is important to establish and
26 maintain a significant level of understanding of, and trust in, the decisions and
27 associated implementation efforts. Full engagement by all MRRIC members in the AM
28 process is not feasible; however, it is essential that opportunities exist for members to
29 stay engaged and share their perspectives. In addition to active participation as
30 members of the WGs, the agencies will afford opportunities for interested MRRIC
31 members to observe key Team meetings without the attendant commitments required of
32 WG members. It is possible that interest and participation during initial implementation
33 is higher than ultimately optimal for efficient WG function but will serve to increase
34 trust in the process. Therefore, early involvement should be accommodated to the
35 extent possible, with a longer-term aim to reduce the group size to an optimum.

1 The Bird, Fish, and HC WGs may function as subgroups of the SAM; the agencies and
2 MRRIC will collaborate during the transition period between issuance of the DEIS and
3 the ROD to refine the composition and operation of the WGs. MRRIC may retain other
4 existing Task Groups or sunset those no longer required, and may establish new Task or
5 Ad Hoc Groups as needed to address specific issues related to the AM program (with
6 consideration for maintaining a total number of subgroups commensurate with the
7 available budget and for the time commitment of members and agency staff).

8 **Note:** WG members will be expected to commit to the time and effort
9 necessary to effectively engage in the deliberations of the Teams. It will be
10 important to establish reasonable expectations of members and enforce
11 them. It is not yet clear if the members would be reimbursed for time, travel
12 or other expenses associated with these efforts – doing so may necessitate
limits on the number of members on each WG.

12 2.3.7.3 Independent Advisory Panel

13 For the last several years, the MRRP has had both an Independent Science Advisory
14 Panel (ISAP) and an Independent Social Economic Technical Review (IETR) Panel.
15 This structure should be retained during the transition from the DEIS through the ROD.
16 Going forward, it is proposed that the MRRP will maintain a single Independent
17 Advisory Panel (Panel) that is convened, as necessary, to provide independent scientific
18 and socio-economic peer review of work products or to analyze and interpret data. The
19 Panel may be composed of sub-Panels as needed to accomplish their charge. This
20 structure will allow for greater integration across disciplines and more efficient and
21 effective communication with the agencies and MRRIC.

22 The Panel may review the monitoring and assessment results, research plan, WP, and
23 other relevant materials, or provide expert scientific and socio-economic advice and
24 recommendations to MRRIC, its WGs, and the agencies. Execution of these functions,
25 within the scope of their contract and subject to the availability of funds, is necessary for
26 the proper function of the AM Program and for building trust between the agencies and
27 stakeholders. The Panel has been and will be managed by a Third Party Science Neutral
28 (TPSN) party that maintains Panel membership to ensure appropriate expertise is
29 provided, receives tasks from the agencies or MRRIC, and ensures their activities are
30 within the mandates and the scope of the AM Plan (see Section 2.3.7.4). In accordance
31 with this AM Plan, the TPSN refrains from any reviews and remains neutral on products
32 of the Panel.

1 The size and composition of the Panel, as well as their role and level of engagement,
2 should be periodically reviewed and updated to ensure maximum benefit to the
3 Program. Presently, the Panel should be comprised of between six to eight science
4 advisors that, in addition to other specific tasks, attend the annual Fall Science Meeting
5 and the AM Workshop and meet with the full MRRIC at least twice annually. The TPSN
6 ensures that expertise on the standing panel meets current and projected Program
7 needs, and generally includes the following disciplines: Aquatic/Riverine Ecology, River
8 Geomorphology/ Hydrology, Least Tern/Piping Plover Specialist, Sturgeon Specialist,
9 Quantitative Ecology/Statistics, Conservation Biology, and Socio-economics. An
10 individual member can fulfill more than one of the aforementioned areas of expertise,
11 and Panel size should be regulated accordingly, if possible. The Panel is charged with
12 independent science support and technical oversight by providing objective advice on
13 specific topics originating from the agencies and/or MRRIC. Interaction with the Panel
14 must be within the scope of their contract, subject to the availability of funds, and must
15 identify specific tasks, products, and timelines. To ensure such interactions meet
16 contractual requirements and are documentable, the following definitions will be used:

- 17 • **Panel-Initiated Communication.** If the Panel considers a topic of sufficient relevance
18 in their role of reviewing and providing independent scientific advice on draft
19 products regarding implementation of the Panel recommendations or MRRIC
20 proposed actions, they may provide written advice or guidance to MRRIC and the
21 AM Teams. Their advice would be provided through the TPSN to the appropriate
22 WG, MRRIC, or the agencies for consideration.
- 23 • **Inform.** Through the appropriate MRRIC WG, the agencies will provide information
24 to the TPSN to assist Panel members in understanding the problem being addressed,
25 the options being considered, and the final decision to be made. The agencies will
26 keep the TPSN informed of the final decisions. The task for the Panel is to review
27 materials as time permits.
- 28 • **Discuss and Provide Feedback.** Through the appropriate work WG, the AM Teams or
29 Technical Team may interact directly with the Panel on a “scientist-to-scientist”
30 basis. During meetings (web or face-to-face), the Teams will seek verbal feedback
31 (e.g., clarification questions, initial reactions, and/or a general sense of direction and
32 progress) from Panel members. The Teams will consider the feedback and then
33 apprise the TPSN and MRRIC (or appropriate WG) as to how the feedback was used.
34 Panel member verbal feedback should be considered informal and does not
35 necessarily represent a consensus statement from the Panel. Documentation of the
36 exchange during the calls/meetings will be provided through meeting summaries.
- 37 • **Evaluate.** Through the appropriate WG, the AM Teams will interact directly with the
38 ISAP seeking a collective opinion. Any document(s) for review and necessary
39 background information will be shared with the Panel along with a specific review

1 question (or set of questions). Discussion and feedback between the Panel and
2 MRRIC and the relevant AM Team is inherently part of the “evaluate” option. The
3 expected Panel product is a written memo reflecting the collective opinion of all
4 Panel members in response to the review question(s), which will be considered by
5 the AM Teams. The Agency response will be shared in a written memo indicating
6 how the opinion was used/will be used.

7 Independent advice and reviews provided by the Panel are scientific, while decision-
8 making and policy interpretations are left to the USACE after consideration of
9 consensus recommendations from MRRIC. The AM Teams, particularly the Technical
10 Team, interact with the Panel on an as-needed basis, but at least annually as part of the
11 AM Workshop. Interactions occurs through/with the appropriate MRRIC-designated
12 WG. Requirements of the Panel and procedures for its interactions with the MRRIC and
13 the AM Teams are provided in Attachment 11 of Appendix A.

14 **2.3.7.4 *Third Party Science Neutral (TPSN)***

15 The TPSN is responsible for selecting and managing the Independent Science Advisory
16 Panel (ISAP), the Independent Social Economic Technical Review (ISETR) panel, and
17 the proposed consolidated Panel, including liaising between the Panel and the MRRIC,
18 the USACE, and USFWS (see Section 2.3.7.3 and Attachment 15 of Appendix A). The
19 TPSN follows guidance from the National Academy of Science (2003) when developing
20 the panel(s).

21 MRRIC and/or the USACE work directly with the TPSN, to develop topics and questions
22 to be addressed by the Panel. This charge includes instructions to the panelists
23 regarding the topic, expected products, task timelines, and how panel deliberations will
24 be conducted. The TPSN facilitates all Panel deliberations and keeps the panelists on
25 track. All communication regarding the topics under consideration between the USACE,
26 MRRIC members, and candidate or selected panelists, is coordinated through the TPSN.

27 The TPSN ensures full consideration of multiple perspectives on the issues and a
28 structured process that guarantees the integrity of an independent review, avoids bias,
29 and guides communications between Panel members and the USACE, MRRIC, and
30 other interested parties.

31 **2.3.7.5 *Interactions with MRRIC***

32 Interaction between the agencies and MRRIC are defined in the Operating Procedures
33 (MRRIC 2016; amended 2016; See Attachment 1, Appendix A), and consist of one-way
34 (inform) and two-way communications (with low, medium, and high collaboration). In

1 February 2011, MRRIC approved an engagement approach describing how the agencies
2 would interact with MRRIC in developing and implementing AM strategies for the
3 MRRP. The approach was developed to ensure timely exchange of information and
4 development of products, while providing opportunity for appropriate interaction
5 between MRRIC and the agencies at key stages in the development, implementation,
6 and decision-making involved in the AM process. The engagement with MRRIC on the
7 development of the MRRMP-EIS and this AM Plan used this approach, and it remains
8 an effective mechanism for engagement during AM implementation. The intention of
9 the approach is the following:

- 10 1. Be understood and trusted by MRRIC members.
- 11 2. Provide a satisfactory level of participation in the systematic process for MRRIC
12 members.
- 13 3. Provide an opportunity for MRRIC to identify any social, economic, or cultural issues
14 that may result from the proposed action(s).
- 15 4. Be implementable for both the agencies and MRRIC.
- 16 5. Be focused on resolving scientific uncertainties necessary to inform management
17 decisions.
- 18 6. Provide for collaboration that allows the agencies to implement the MRRP in a
19 timely manner.

20 AM strategies require highly interactive and timely deliberations. To address this
21 requirement, the approach established that engagement is to be conducted primarily
22 through the MRRIC WGs. Agency leads and the AM Teams interact directly with the
23 WGs through conference calls, webinars, and in-person meetings. Implementation of
24 the approach is expected to work as follows: the WGs identified in Section 2.3.7.2 work
25 closely with and at times as a part of their corresponding agency AM Teams. The
26 primary interactions center on the Fall Science Meeting, the AM Workshop, and the WP
27 development, but the Teams will meet at other times as needed to ensure the necessary
28 collaboration and communication occurs. MRRIC WGs have the responsibility to engage
29 with agency personnel on the Teams and reach into the broader MRRIC to solicit input
30 and promote understanding and support for activities and products. WG and Agency
31 briefings will occur at key points to ensure the full MRRIC stays informed.

32 Communications between the agencies and MRRIC are classified by the level of
33 collaboration (as low, medium, or high). More medium- and high-level collaboration is
34 likely to occur in implementation of the AM Plan, especially among the AM Teams and
35 the MRRIC WGs and early in implementation of the Program. The appropriate types of
36 interactions would depend on the nature of the issue and the groups involved. These
37 interactions may vary over time as well; e.g., an issue initially treated using low-level

1 collaboration may later require a medium-level of collaboration. Thus, a mechanism to
2 change the designated level or the flexibility to adjust the associated collaboration is
3 needed. A summary of potential interactions follows:

- 4 • Inform. The AM Bird, Fish, HC and Management Teams will provide information to
5 MRRIC to assist members in understanding the program performance, results of key
6 analyses, alternatives considered, problem being addressed, the status of and
7 predictions for population and system status, and other pertinent information about
8 the Program. Interactions at the Inform level will rely on the WG Representatives as
9 well as e-mail and web meetings to inform the MRRIC. The agencies will inform
10 MRRIC of any Oversight-level decisions regarding program implementation. The
11 Technical Team will provide information to MRRIC and the Panel through the
12 appropriate WG to assist Panel members in understanding the problem being
13 addressed, the options being considered, and decisions that need to be made.
- 14 • Low Collaboration. As the AM Bird, Fish, HC and Management Teams “inform”
15 MRRIC of the above issues during facilitated meetings and plenary meetings of
16 MRRIC, they will also seek feedback from MRRIC. Concerns expressed are taken
17 into consideration prior to making decisions regarding the issues discussed, and the
18 use of the input is addressed at the next Team meeting and the next MRRIC plenary
19 meeting. Input from MRRIC WGs during Team meetings is included in summary
20 reports for those meetings produced by the facilitator.
- 21 • Medium Collaboration. The AM Bird, Fish, HC and Management Teams will work
22 directly with their associated MRRIC WGs on monitoring and assessment activities
23 and research for the MRRP. This interaction occurs at the Fall Science Meeting and,
24 Annual AM Workshop, and any other scheduled meetings for this purpose. MRRIC
25 WG input is included in the Joint Report, and the facilitator shares WG
26 recommendations with the full MRRIC through meeting minutes, recordings,
27 presentations, or other means. The Teams will ensure concerns and suggestions are
28 understood, and will try to address those concerns to the extent possible within legal
29 and policy constraints. The WGs then communicate to MRRIC and any appropriate
30 Task or WG describing how their concerns were addressed.
- 31 • High Collaboration. The AM Bird, Fish, HC and Management Teams will work
32 directly with appropriate MRRIC WGs on certain decisions and recommendations,
33 within legal and policy constraints. A high level of collaboration occurs on the
34 development of the WP, new or controversial information, research and project
35 implementation priorities, etc. The Teams, including their member MRRIC WGs,
36 jointly explore potential solutions and seek agreement on critical issues. The Teams
37 will elevate any concerns or recommendations to the appropriate agency decision
38 entity, and will provide related briefings to the MRRIC. The WGs, in turn, provide

1 their feedback to the full MRRIC and seek agreement (consensus) on
2 recommendations to the agencies.

3 Interactions with MRRIC are intended to fall under the same laws and acts that
4 currently guide the Committee and agencies (e.g., Sec. 5018, FACA, WRDA).
5 Notwithstanding the cooperative nature of the Program, the lead agencies (USACE and
6 USFWS) have statutory responsibilities that cannot be delegated and the program
7 structure and interactions are intended to promote collaboration and MRRIC input to
8 decisions. Generally, the recommended interactions provide for the following:

- 9 • MRRIC WGs engaging with agency Birds, Fish and HC Teams to assess the latest
10 scientific data/findings, provide input on monitoring, assessment, research and
11 implementation issues, and help decide which issues should be elevated to the full
12 Committee
- 13 • MRRIC as a whole to be directly informed about the team process by those members
14 participating in the species- or HC-specific teams (rather than solely by agency
15 staff/contractors)
- 16 • MRRIC as a whole involved in the AM learning process and in the formation of
17 recommendations for actions and research
- 18 • MRRIC members to remain informed of significant findings through attendance at
19 the AM Workshop and other interactions during the year so they can be informed
20 prior to plenary meetings
- 21 • Access by MRRIC members to monitoring results and research findings through
22 data-sharing and program reports
- 23 • MRRIC as a whole to examine the science process and provide recommendations for
24 the current (implementation) and next year's (development) WP, and for the 3-5
25 year strategic plan
- 26 • MRRIC as a whole to evaluate the AM program performance and make
27 recommendations for changes to improve performance, accountability, etc.

28 MRRIC meets nominally three times per year to develop recommendations, building on
29 the results of MRRP WP implementation and reports from the Bird, Fish, and HC
30 WGs/Teams. Additional meetings can be called as needed, subject to available resources
31 and other relevant considerations. Use of a conference call meeting may be required
32 occasionally, but would likely be convened only to reach final consensus on a
33 recommendation that MRRIC already reached tentative consensus on during a face-to-
34 face meeting. MRRIC members may also attend the Annual AM Workshop, as well as
35 participate in Annual Forum and Draft WP Review Webinar, as well as any other
36 webinars/calls established to brief MRRIC.

1 The interaction strategy described above is intended to permit a consensus
2 recommendation(s) on the MRRP WP in a more compressed timeframe than has
3 historically been employed. This would maximize the effectiveness of the MRRIC's input
4 to the budget and WP processes. A tentative face-to-face plenary meeting schedule with
5 general agenda items is provided below. The timing of each meeting will need to be
6 refined as understanding of the Program's implementation increases and, concurrently,
7 the ability for MRRIC to have the most impact and influence through their
8 recommendations is best understood:

- 9 o Meeting #1 (in October/November) which would provide an opportunity to
10 discuss preliminary results of implementation efforts the prior year and
11 information gained from the monitoring efforts and discuss other issues as
12 appropriate (e.g., strategic priorities, programmatic considerations)
- 13 o Meeting #2 (in mid- to late-March) which would provide an opportunity to
14 engage on traditional "Annual Forum" agenda items (science presentations and
15 review of the Corps' draft WP), for MRRIC to begin identifying potential areas for
16 recommendations
- 17 o Meeting #3 (in late-May) which would provide an opportunity to reach tentative
18 consensus on recommendations related to the Corps' draft WP, hear updates on
19 implementation of the AM activities, and discuss other issues as appropriate
20 (e.g., strategic priorities, programmatic considerations)

21 **2.3.8 Basin states, other Federal agencies, and tribal roles outside the MRRIC
22 collaborative process**

23 Involvement by any Federal Agency, State and Tribe in MRRIC does not change or affect
24 any other authorities relating to these groups. The MRRIC Charter specifically describes
25 the intention to not interfere with these outside processes, stating:

26 Participation in the Committee by Tribal entities does not substitute for
27 nor replace federal requirements to consult with Tribal entities pursuant
28 to federal laws and regulations, such as: Executive Order 13175, Tribal
29 Consultation; any federal agency's trust responsibilities to a federally
30 recognized tribe in the Missouri River Basin or a tribe that has historically
31 been on the Missouri River; and/or replace any treaty or right thereof such
32 as: the Portage des Sioux Treaty (July 1815); the Treaty of Ft. Laramie, 11
33 Stat. 749 (Sept 17, 1851); the Treaty with the Omaha, 10 Stat. 1043 (March
34 16, 1854); the Treaty of Ft. Laramie, 15 Stat. 635 (April 29, 1868); Title VI-
35 Cheyenne River Sioux Tribe, Lower Brule Sioux Tribe, and State of South
36 Dakota Terrestrial Wildlife Habitat Restoration Act of the Omnibus
37 Consolidated and Emergency Appropriations Act of 1999, PL 105-277, 112
38 Stat. 2681, 2861-660-670 (October 21, 1988), as amended by Title IV of
39 the Water Resources Development Act of 1999, PL 106-53, 113 Stat 269,

1 385-397 (August 17, 1999), and as otherwise amended; and any other
2 treaty or right. Cooperation with the federally recognized tribes engaged in
3 this process should be interpreted as "in good faith."
4

5 Participation in the Committee by State, Tribal, or Federal entities does
6 not limit their discretion; alter, affect, impair, delegate, or relinquish their
7 statutory or other legal rights and responsibilities, including any right to
8 legal remedies; or otherwise waive their sovereign immunity under
9 applicable law; create any new right to any type of administrative review or
10 create any new right to judicial review or any other right or benefit,
11 substantive or procedural, enforceable by or against these entities or any
12 other stakeholder participating in the Committee; and affect Tribal
13 reserved water rights, treaty rights, or water rights administered by the
14 Tribes and/or States, including the "Winters' Doctrine", Winters v United
15 States, 207 U.S. 564 (1908). If the processes and procedures of the
16 Committee would impede the implementation of any action for which
17 agencies of the States, Tribes, or United States are obligated under law,
18 that agency reserves the right to proceed with fulfilling those obligations in
19 such manners as it may deem appropriate. (MRRIC 2009).
20

21 Similarly, the governance of this adaptive management plan cannot impede or interfere
22 with any other right of responsibilities of these groups. Rather this AM Plan describes
23 the roles of Agencies, States, and Tribes specifically within the MRRIC framework.
24 MRRIC designed to be an additional forum for these groups to provide valuable insight
25 on the management and operations of the MRRP. Additionally, the expertise of these
26 groups may be utilized by the various work groups and implementation teams. These
27 new forums for collaboration between USACE and Federal Agencies, States and Tribes
28 provide an important additional opportunity for communication and collaboration
29 while protecting any outside processes.

30 2.3.8.1 States

31 Each state has responsibilities through various federal and state statutory and
32 constitutional authorities, for management of water quantity, water quality, and fish and
33 wildlife resources within their boundaries that could be affected in this process (in
34 either a positive or negative way). As previously stated this governance structure does
35 not change or impede any of the rights and responsibilities of a state codified by law.

36 Historically, it has been the role of the state fish and game agencies to assist in putting
37 projects on the ground. The USACE and USFWS will continue to plan site-specific
38 projects with State input and continue to coordinate with the appropriate state agency
39 on any and all legal requirements for comment, collaboration, certification, permitting,
40 etc. One statutorily protected consultation role of note is the Fish and Wildlife
41 Coordination Act (FWCA). Under the FWCA, USACE is required to coordinate with the

1 state game and fish agencies and the USFWS for site specific projects. USACE will
2 continue to execute the FWCA in accordance with the National MOU between the
3 USFWS and the USACE. As described in the National MOU, the USFWS will coordinate
4 with state game and fish agencies and provide consolidated comments to the USACE via
5 a planning aid letter as required by the FWCA.

6 With regard to the regulation of the Missouri River Mainstem Reservoir System, the
7 USACE will continue to provide a draft Annual Operating Plan (AOP) each fall that
8 describes the planned operation of the reservoir system for the coming year under a
9 variety of runoff conditions. The States will have the opportunity to provide comments
10 on the draft AOP at the fall public meetings or by providing written comments during
11 the comment period. Another outside process for states to comment on any issue
12 related to the Management Plan or ongoing AM process is via official letter, which can
13 be submitted to the USACE at any time.

14 The AM plan contemplates that the States will have an additional role through their
15 representation at MRRIC. It is imperative that MRRIC State representatives are able to
16 effectively relay information presented as MRRIC to interested state agencies and bring
17 their concerns back to the MRRIC table. MRRIC representatives will be able to reach a
18 broader group of interests than the outside statutory structure contemplates being able
19 to inform decisions. State agency expertise also has a potential role to play on various
20 work groups.

21 *2.3.8.2 Federal Agencies*

22 Federal agencies are not counted for purposes of Committee quorum requirements and
23 do not participate in the determination of consensus recommendations, however,
24 agency representatives provide input on substantive issues where they have jurisdiction
25 or special expertise and are therefore integral to the AM Process. Like states and Tribes,
26 Federal agencies are consulted on site-specific projects when they have special expertise,
27 statutory responsibilities or authorities. The National Park Service, for example, will
28 continue to be involved in assisting the agencies in planning sandbar habitat
29 construction activities in the Missouri River National Recreational River (MRNRR)
30 reaches below Fort Randall and Gavins Point Dams. Federal agency consultation in this
31 capacity should occur early in the project formulation process through interactions and
32 discussions during meetings of the Bird and Fish Teams.

33 *2.3.8.3 Tribes*

34 Tribal members of MRRIC have created a Tribal Interests WG, which provides a venue
35 for collaborating with Tribes on MRRP work products and specific tribal interests and

1 have these taken into consideration in relation to MRRP activities. The MRRP has a
2 Tribal Lead who coordinates MRRP developments directly with all tribal nations and
3 strives to ensure their councils are aware of proposed budgets and activities. A key
4 responsibility is to communicate concerns expressed by individual tribal nations about
5 specific actions or projects to MRRP management for consideration. The Tribal Lead
6 coordinates resolution of issues, recognizing not all requests can be accommodated, and
7 provides feedback to the requesting tribe. For those tribes unable to have representation
8 at each MRRIC meeting, the Tribal Lead strives to ensure tribal governments receive
9 information discussed at these important stakeholder meetings and that they are aware
10 of pending opportunities to provide input to the process. The MRRP will coordinate
11 with the Tribal Lead to make sure information regarding the Program is communicated
12 with the tribes, either through MRRIC or directly via the Tribal Lead.

13 **2.4 AM Decision process, critical engagements, and workflows**

14 **2.4.1 Overview of the MRRP AM decision process**

15 The decision process for the MRRP includes the mechanisms by which information
16 about project and program performance, species status, system state, and other
17 knowledge is gathered and evaluated, shared with agency managers, MRRIC, and
18 stakeholders, and used to make improved implementation decisions. The process is
19 constrained by the timing of budget cycles, construction windows, and information
20 availability; by the resources necessary for data processing, QA, analysis, and
21 interpretation; by the need for coordination and communication; and by external factors
22 like regulatory compliance issues.

23 The process is outlined in a series of diagrams and timelines that identify the needed
24 decision-making steps, who is responsible for those steps, and when they occur. (see
25 Section 2.4.2 – 2.4.6). The process is built around the review of information and
26 application of learning to the development of the WP. The overall process includes
27 several important products and critical engagements that are consistent from year-to-
28 year, but the specific steps can vary considerably depending upon the decision under
29 consideration. The decision process was developed to be as follows.

- 30 • **Science-Driven.** Decisions are based on the ongoing testing of hypotheses and active
31 development, incorporation, and communication of new decision-relevant
32 information arising from research, monitoring, and assessment efforts.
33 • **Collaborative.** MRRIC and its WGs are engaged at several points in the process to
34 ensure their access to the latest information and to obtain their input in all key
35 decisions.

- 1 • Efficient. Recommendations and decisions are made as close to the implementation
2 level as possible and elevated to higher levels only when programmatic or policy
3 authority is required.
- 4 • Specific. The process steps, products, needed engagement and level of decision
5 making are defined explicitly for a range of decisions and vary by decision scope.
- 6 • Comprehensive. A range of decisions, including ones likely to be rare, are considered
7 in advance to reduce programmatic uncertainty and increase efficiency through the
8 development of contingency plans, where warranted.
- 9 • Transparent. The decision process requires that information is shared in a timely
10 and understandable manner, and MRRIC participates in the process at all levels.

11 The USACE Civil Works budget process and the AOP for the reservoir system play an
12 important role in defining the basic MRRP decision process (see Section 2.2.2). A
13 “Science Update” process, which occurs annually and is the primary means by which
14 scientific information is synthesized, hypotheses are assessed, and the results are
15 communicated, including collaboration across various participants in the governance
16 process (see Section 2.4.3). The WP development process, described in Section 2.4.4,
17 includes sub-processes for information development, sharing, and decision making that
18 vary depending on the specific issue being addressed. These are described using a set of
19 decision workflow diagrams that provide a visual comparison of the steps in each
20 decision and the level of engagement with each governance level for different types of
21 decisions (see Section 2.4.6). Should knowledge gained from AM indicate the need for
22 new management actions the necessary steps, engagements, and decisions are described
23 (see Section 2.4.5).

24 **2.4.2 Basic Annual AM engagement process**

25 The annual engagement process for the MRRP revolves around science updates and the
26 generation and sharing of information about program performance, then using that
27 information for the development/adjustment of the WP. Figure 16 provides an overview
28 of the process, which recurs each year for the Program. The elements in the figure are
29 described in the following sections. While the description below provides the basic
30 process as it relates to the information exchange between the agencies and MRRIC
31 regarding decisions on the WP, embedded within are a number of additional decision
32 processes, many of which are described in the remainder of Chapter 2 and in key
33 sections of Chapters 3 through 5. Each process or input flow between major decision
34 points or events (e.g., draft or final documents, meetings, webinars) is described with an
35 associated colored symbol, and combined into a cohesive workflow diagram (Figure 15,
36 see Sections 2.4.2.1 – 2.4.2.4).

1 2.4.2.1 Annual operations planning cycle

2 **Draft AOP Meetings** – Annual public meetings held in October by the
3 USACE around the Missouri River basin to present and receive feedback
4 on the draft AOP for the upcoming calendar year.

5 **Draft AOP** – Draft AOP prepared by the USACE Water Management office
6 annually based on the draft WP

7 **Final AOP** – The finalized AOP based on the approved WP and issued by
8 the USACE Water Management office in December of each year for the
9 following calendar year.

10 **Final AOP Meetings** - Annual public meetings held in April by the USACE
11 around the Missouri River basin to present the final AOP for that year's
12 water management operations.

13 2.4.2.2 Monitoring, evaluation, and engagement with the Bird, Fish, and HC Teams

14 **Fall Science Meeting** – A Fall science meeting would be held for agency
15 technical staff and MRRIC WGs to be briefed on research and monitoring
16 findings (see Section 2.4.3.1).

17 **Bird, Fish, and Management Team Calls** – Conference/webmeetings held
18 throughout the year to review and discuss information, develop
19 recommendations, and plan for and follow up on in-person meetings.

20 **Draft AM Report** – Summary of monitoring and assessment results,
21 research, and new information relevant to the MRRP.

22 **Annual AM Workshop** – Annual meeting where primary exchange of
23 information between scientists and decision makers occurs. Includes close
24 collaboration with MRRIC WGs with input from agency AM Teams and
25 MRRIC on priorities for the WP (see Section 2.4.3.2).

31 **Bird, Fish, HC and Management Team Meetings** – Following the AM
Workshop, the Bird, Fish, and HC Teams meet to deliberate on lessons
learned, to develop priorities, and to prepare a report of other factors.
Included are recommendations for adjustments to the current FY and
FY+1 activities, with an emphasis on the FY+2 and strategic (FY+3 and
FY+4) recommendations.

1 
2 Teams' Joint Report – (Optional) Includes a synthesis of MRRIC WG
3 assessments of Program performance, research, and prioritized
4 recommendations from the Bird, Fish, and HC Teams, and draft WP input
from the Management Team.

5 
6 Final AM Report – The Management Team integrates input from the
7 Technical and species teams, with input from the HC WG. They consider
8 budget, AOP, and other constraints and make recommendations on the
WP.

9 2.4.2.3 WP development

10 
11 Draft WP – The draft WP is prepared/updated by the Management Team
12 based on the recommendations of the Implementation Teams, the HC WG,
budget, and acquisition constraints and needs.

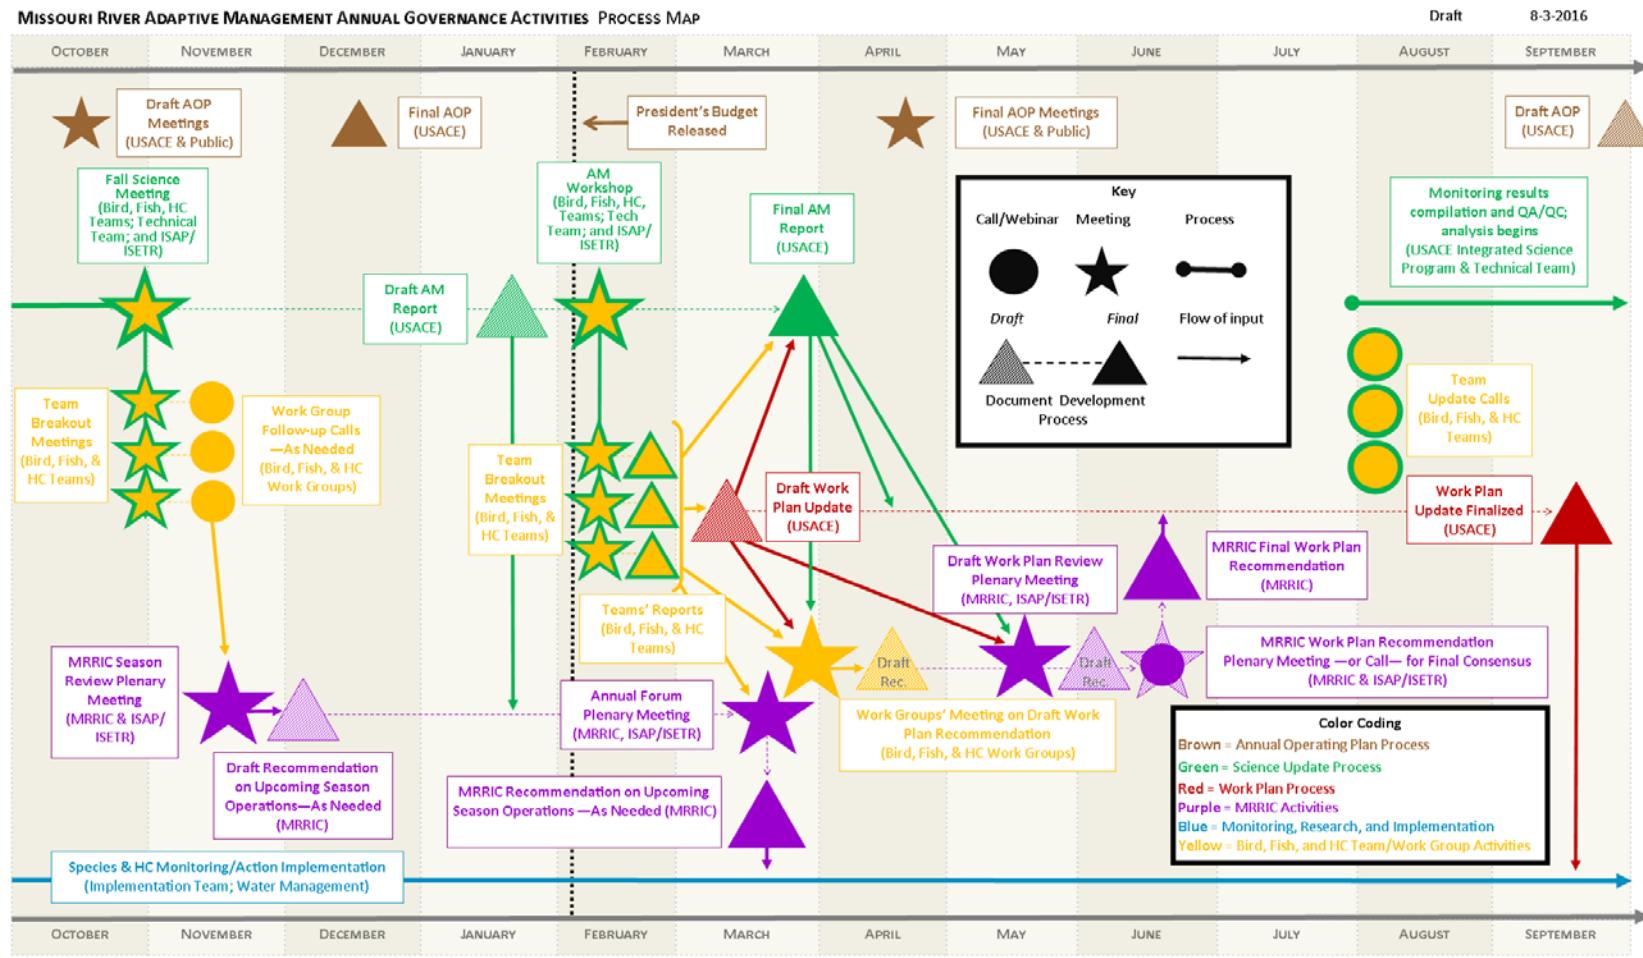

13 
14 Final WP – The final WP update is made in June each year following input
15 from all the teams and MRRIC recommendations. Updates to the plan
16 emphasize FY+2 actions, but include adjustments to other years and add
17 FY+4 strategic projections. WP implementation begins October 1 each
year.

18 2.4.2.4 MRRIC meetings and products

19 
20 MRRIC Meetings – Three in-person meetings of the full MRRIC would
be held annually, with a fourth date reserved as needed. Options for
meetings using web and telephone are being considered. Includes an
Annual Forum for MRRIC to present the final AOP for that year's water
management operations and key lessons from the science update process.

24 
25 MRRIC Recommendations – The MRRIC typically provides
recommendations on the WP in June of each year. Recommendations
focus on FY+2 Program needs, but can include adjustments to other years
and strategic plans for FY+3 and FY+4.

28 
29 MRRIC Calls – (Optional) A webinar is scheduled in April/May to discuss
issues related to the WP development process.

This process map depicts the proposed governance activities to be undertaken annually by the U.S. Army Corps of Engineers (USACE), the U.S. Fish and Wildlife Service (USFWS), and the Missouri River Recovery Implementation Committee (MRRIC) in the implementation of Adaptive Management (AM) related to the endangered piping plover and pallid sturgeon in the Missouri River. This process map reflects the governance recommendations developed by the MRRIC AM Ad Hoc Group for consideration by MRRIC in August 2016.

2 Figure 16. Proposed governance activities to be undertaken annually by the USACE, the USFWS, and the MRRIC in the implementation of AM for the
3 MRRP. This process map reflects the governance recommendations developed by the MRRIC AM Ad Hoc Group for consideration by MRRIC in August
4 2016. Additional description of labeled symbols provided in Sections 2.4.2.1 – 2.4.2.4.

1 **2.4.3 Science Update process**

2 The Science Update process (Figure 17) occurs annually, in coordination with the WP
3 update process. This process provides several points of interaction across the levels of
4 governance and with stakeholders to ensure analyses and resulting findings are timely,
5 decision-relevant, and adequately communicated. It also provides a forum for
6 collaboration within the AM learning process through research and system evaluation.

7 The Science Update process begins when system-wide and action-specific monitoring
8 data becomes available, along with preliminary after-action assessments. A Fall Science
9 Meeting (see Section 2.4.3.1) is held to review initial observations from the field season,
10 identify analytical needs with a focus on the AM workshop, and review the Strategic
11 Plan. The Technical Team performs necessary data analysis and synthesis to evaluate
12 action effectiveness and the habitat and species status and needs. The Team conducts
13 any additional analyses as requested by the ISP Manager or Bird, Fish, HC, and
14 Management Teams, and as approved by the SPM. The Technical Team prepares a draft
15 AM report and any additional reports as tasked.

16 The Technical Team shares their draft AM report in advance of the AM Workshop,
17 which is attended by the Bird, Fish, HC, and Management Teams, leadership at the
18 Oversight level, and the Panel, as well as MRRIC members interested in hearing the
19 presentations and discussion. The Workshop provides an opportunity for
20 communication and discussion among technical staff, decision makers, and
21 stakeholders regarding species and habitat status and needs, hypothesis evaluations,
22 proposed adjustments to research and monitoring, and the application of findings to
23 System management. Feedback received during the meeting and from follow-up
24 meetings may lead to revisions to the Technical Team's annual AM report.

25 Following the completion and dissemination of the annual reports addressing research,
26 monitoring, and assessment, a summary of the related information is presented at the
27 Annual Forum for MRRIC to summarize species status, science findings, and
28 management implications. Other specific presentations by researchers or technical staff
29 as identified by the Bird, Fish and HC WGs are also be delivered at the Annual Forum.

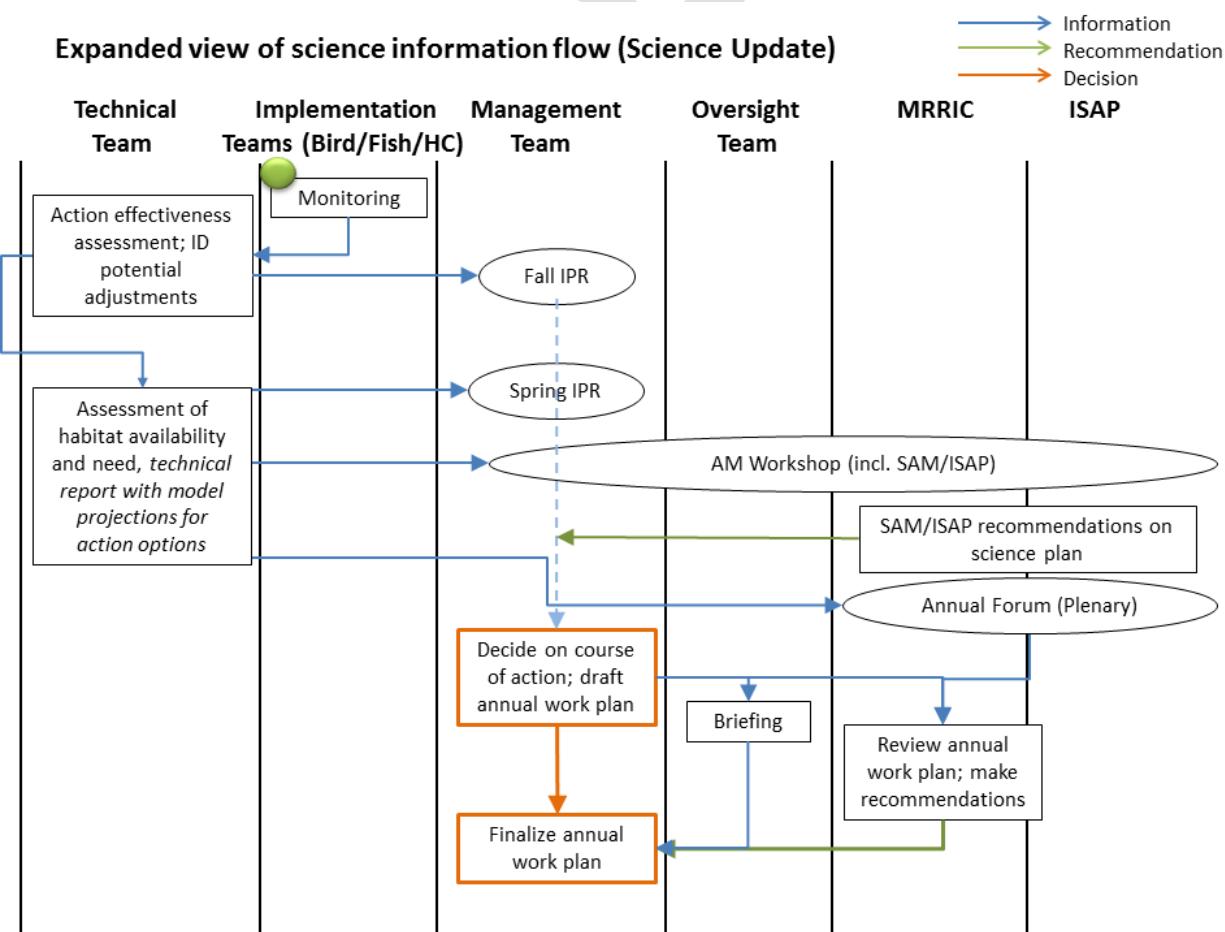

30 Two In-Progress Review (IPR) meetings are held annually to permit researchers to
31 share initial findings and obtain feedback from the ISP Manager, Panel, and other
32 researchers. The fall IPR is held in conjunction with the Fall Science Meeting. The
33 spring IPR is held in conjunction with the Annual AM Workshop, during which the
34 major science findings are presented (see Section 2.4.3.2). The ISP is responsible for
35 coordinating and conducting the IPR portion of the Annual AM Workshop. The IPR may

- 1 include reporting and feedback on major studies not considered “research” in order to
- 2 discuss assessment needs and adjustments based on new information.

- 3 Findings from the IPRs and AM workshop are used by the Bird, Fish, HC, and
- 4 Management Teams and Oversight to identify needed adjustments to the WP, as well as
- 5 adjustments to research and monitoring as deemed necessary.

- 6 Figure 18 highlights the IPRs, AM Workshop, Annual Forum, and Missouri River
- 7 Natural Resources Conference (MRNRC) as well as showing the timeline for fish and
- 8 bird monitoring. An “other” category is included for MRNRC and the Water
- 9 Management briefing to indicate the role of researchers and the public. The WP process
- 10 is retained in this graphic for reference; the key meetings occur in time to help the
- 11 managers draft the WP and to provide MRRIC the information necessary to review the
- 12 WP and make recommendations based on science progress.

4 2.4.3.1 Fall Science Meeting

5 2.4.3.1.1 Purpose, scope, and timing

6 The Fall Science Meeting will be held the third week of October¹ each year to provide a
 7 regularly scheduled, focused opportunity for the Technical Team, Bird and Fish Teams,
 8 HC Team, other MRRIC WGs, and agency Management and Oversight to meet, hear
 9 about, question, assess, and understand the technical results and implications of AM
 10 Plan implementation efforts. In particular, the Fall Science Meeting is intended to (a)
 11 serve as an in-Progress Review (IPR) for ongoing research and technology development
 12 activities, (b) provide opportunities for field crews to share early observations regarding
 13 system conditions, project performance, and monitoring activities, and (c) identify and
 14 assign additional analyses needed for the upcoming AM workshop, and (d) allow Water
 15 Management to provide a briefing on the draft AOP and receive feedback relative to
 16 MRRP needs. The meeting provides MRRIC WGs with face-to-face opportunities to
 17 discuss the observations of technical staff involved in the MRRP and implications for
 18 potential management action needs. Finally, the event provides the attendees an
 19 opportunity to continue building trust in the process and maintains transparency in
 20 information sharing and decision making.

21 2.4.3.1.2 Attendees

22 The Fall Science Meeting is a facilitated, 4-day meeting of key personnel and groups
 23 involved in collecting and assessing scientific data for the MRRP, or conducting research
 24 for the MRRP, or responsible for developing recommendations or making decisions
 25 based upon scientific information.

26

27

¹ This date is a placeholder in AMP V5. Actual dates will be adjusted as needed for the Final Draft.

- 1 Mandatory attendees include the following:
- 2 • The Facilitator,
- 3 • The ISP Manager,
- 4 • The Lead PI for any research funded by the MRRP,
- 5 • Members of the MRRP Fish, Bird and HC Teams,
- 6 • Members of the MRRP Technical Team so tasked,
- 7 • Members of the MRRP Management Team,
- 8 • MRRIC Bird, Fish and HC WG Chairperson
- 9 • MRRIC Chairperson, and
- 10 • Members of the Panel.

11

12 Those encouraged, but not required, to attend include the following:

- 13 • Members of the MRRIC Bird, Fish and HC WGs¹,
- 14 • Agency staff involved with monitoring or assessment,
- 15 • Other Tribal, Federal or State officials with responsibilities related to project
- 16 implementation, and
- 17 • Agency leadership at the Oversight level.

18 The Fall Science Meeting is open to any member of the MRRIC, other agency or tribe, or

19 general public who wishes to listen to the technical presentations and discussions

20 among participants. Presentations and opportunities for questions and answers (Q&A)

21 are limited to invited attendees in order to adhere to the schedule and achieve meeting

22 objectives.

23 *2.4.3.1.3 Agenda*

24 A draft agenda for the Science Meeting is presented in Attachment 8 of Appendix A.

25 *2.4.3.1.4 Key products*

26 Presentations and abstracts or other related materials from the Fall Meeting are posted

27 on the MRRP website. The Facilitator will prepares a “Meeting Summary” that outlines

28 the primary presentations, issues, and outcomes and makes this summary available

29 prior to the agencies and MRRIC. The Panel prepares responses to any questions posed

30 by the MRRIC or designated WGs. The ISP Manager prepares summary evaluations and

31 recommendations for on-going research and technology development activities.

¹ These groups reflect current proposals developed in interactions between the agencies and the MRRIC AM ad hoc Work Group as of this draft AMP. The final AMP will reflect the selected names/composition, etc., determined by MRRIC.

1 2.4.3.2 Annual AM Workshop

2 2.4.3.2.1 *Purpose, scope, and timing*

3 A facilitated workshop is held in the first week of February¹ of each year to provide an
4 opportunity for agency staff, contractors, and stakeholders to interact and discuss
5 results of research and monitoring efforts for the previous year and plans for the
6 upcoming year. The purpose of the AM Workshop is to report on results of project and
7 Program performance monitoring and promote the exchange of scientific information
8 among technical experts involved with the Program, decision-makers, and stakeholders.
9 Workshop organizers will optimize opportunities for interaction among participants
10 with the aim of supporting program decisions for subsequent years.

11 The Facilitator is responsible for organization of the AM Workshop, which will be held
12 annually at least three weeks prior to the MRRIC Annual Forum and Spring Meeting so
13 that results may be summarized and disseminated prior to addressing the draft WP. The
14 ISP may hold one of the two annual research In Progress Review (IPR) meetings in
15 conjunction with the AM Workshop, provided it does not detract from the agenda.

16 2.4.3.2.2 *Attendees*

17 Mandatory attendees of the AM Workshop include the following:

- 18 • The Facilitator
- 19 • The ISP Manager,
- 20 • The Lead PI for any research funded by the MRRP,
- 21 • Members of the MRRP Fish, Bird and HC Teams,
- 22 • Members of the MRRP Technical Team tasked with presenting information,
- 23 • Members of the MRRP Management Team,
- 24 • MRRIC Bird, Fish and HC WG Members,
- 25 • MRRIC Chairperson, and
- 26 • Members of the Panel.

27 Those encouraged, but not required, to attend include the following:

- 28 • Agency leadership at the Oversight level,
- 29 • Members of the MRRIC,
- 30 • Agency staff involved with monitoring or assessment, and
- 31 • Other Tribal, Federal or state officials with responsibilities related to project
- 32 implementation.

¹ This date is a placeholder in AMP V5. Actual dates will be adjusted as needed for the Final Draft AMP.

1 The AM Workshop is open to any member of the MRRIC, other agency or Tribe, or
2 general public who wishes to listen to the technical presentations and discussions
3 among participants. Presentations and opportunities for Q&A will be limited to invited
4 attendees in order to adhere to the schedule. Senior managers from the USACE vertical
5 team, the USFWS, and MRRIC are encouraged to participate in the AM Workshop and
6 subsequent formulation meetings to ensure that decision making is well-informed and
7 that appropriate guidance is given to the Teams on plan formulation directions
8 (including scopes of other AM applications).

9 *2.4.3.2.3 Process*

- 10 Attachment 8 of Appendix A provides an agenda for the annual AM Workshop.
11 Adjustments to and deviations from the agenda can be made at the discretion of the AM
12 Planning Group in order to accommodate needs, provided required elements are met,
13 including: a) presentations of research results for all funded research activities; project
14 and program performance monitoring and assessment results; results of hypothesis
15 testing; and identified research needs and proposed research and testing activities; and,
16 b) opportunities for agency decision-makers, MRRIC WG members, and the Panel to
17 question researchers and technical personnel making presentations.
- 18 The Facilitator notifies participants and attendees of meeting location and dates at least
19 3 months in advance. A draft agenda is furnished at least 1 month prior to the meeting;
20 adjustments to the specific order or topic of presentations will, as a practical matter,
21 remain subject to change. Presenters provide full presentations and abstracts or copies
22 of reports or other products at least 2 weeks prior to the workshop. Project Management
23 Plans (PMPs) for each study or other research effort provided at the Fall IPR are
24 provided to attendees and should be updated by researchers, as appropriate.
- 25 Presentations are typically 30 minutes, with no more than 20 minutes allotted for
26 presentation (15 minutes preferred), and no less than 10 minutes allotted for questions
27 and discussion. Presentation times can be adjusted to suit specific needs, but
28 opportunities for information exchange in the form of Q&A or open dialogue should not
29 be unduly limited by such adjustments.
- 30 In addition to presentations by researchers and staff addressing specific study efforts,
31 the AM Planning Group schedules a summary presentation of the Program; including
32 expenditures, major initiatives, significant findings, and implications of any significant
33 study results. The MRRP and ISP PMs are responsible for coordinating this summary
34 presentation. Results of solicitations for research needs, research proposals, or other
35 similar efforts are also presented. A targeted summary of the status of any “lines-of-
36 evidence” assessments for pallid sturgeon will be provided.

1 2.4.3.2.4 *Key products*

2 Presentations and abstracts or other related materials from the AM Workshop are
3 posted on the MRRP website. The Facilitator prepares a “Workshop Summary” that
4 outlines the primary presentations, issues, and outcomes and makes this summary
5 available in draft form to the agencies and MRRIC within 2 weeks of the meeting. The
6 MRRIC Bird and Fish WGs will identify, from the presentations delivered at the AM
7 Workshop, a subset of presentations that should be given or summarized at the Annual
8 MRRIC Forum. Selected presenters may also be required to attend the Spring MRRIC
9 meeting and provide presentations or participate in Q&A.

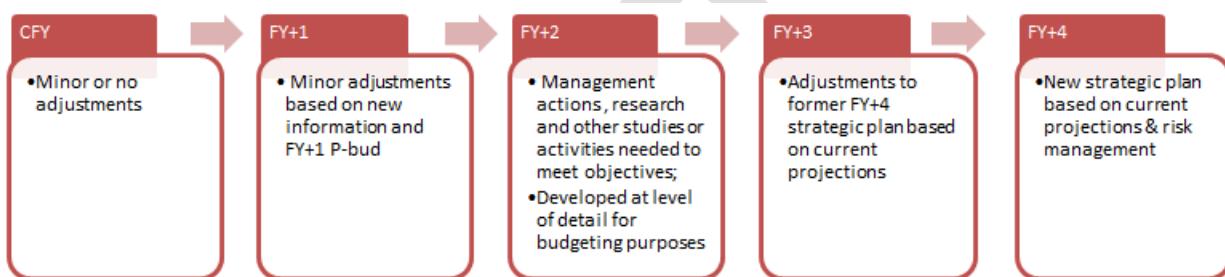

10 2.4.3.3 *Annual Strategic Review*

11 The Annual Strategic Review is the process of developing the Annual Report on the
12 BiOp. As part of that process, AM Annual Reports are prepared by the Technical Team.
13 These reports synthesize information on project actions and monitoring, to assess
14 progress toward program goals, and to describe lessons learned to assist AM Program
15 decisions and to maximize action effectiveness. The four primary report objectives are
16 (1) provide an analysis of monitoring data, especially pertaining to performance of
17 actions relative to the targets, objectives and goals of the MRRP; (2) provide a forecast
18 of outcomes of future management scenarios; (3) outline recommendations for
19 managers and stakeholders; and (4) provide a review of the status of the science,
20 including current published and unpublished research results relevant to management.
21 Results of the Bird and Fish AM Annual Reports are summarized in a Joint Annual
22 Report on the BiOp, which includes input from the MRRIC WGs.

23 The Annual Report, a requirement of the BiOp, documents USACE activities to comply
24 with the provisions of the BiOp, in collaboration with the USFWS and MRRIC. The
25 report includes the activities and progress of the implementation of the elements of the
26 RPA (if any), reasonable and prudent measures (RPMs; if any), and conservation
27 recommendations. The report details the conditions of the river during the preceding
28 year, the impact these circumstances have had on program implementation and listed
29 species, and specific accomplishments. BiOp requirements, population assessments,
30 research and monitoring efforts, and actions taken to meet reporting requirements are
31 specified in the report. Lessons learned and AM strategies with recommendations for
32 future direction of the program implementation are also discussed. The Technical Team
33 is the lead for the report; however, other Teams and agency staff may prepare
34 submissions for inclusion in the report. In addition, the District Implementation PMs
35 produce a report on the current and future plans for implementation of the Mitigation
36 Program, which is included as an appendix to the Annual Report.

1 2.4.4 WP development and approval

2 The MRRP WP is a rolling, 5-year strategic plan for implementation of the management
3 actions, research, studies, and associated engagement process needed to meet the
4 MRRP goals and objectives. The WP follows and builds upon the Science Update
5 Process (see Section 2.4.3), and conforms to the constraints of the USACE Civil Works
6 Budget Process (see Section 2.2.3.1). Annual updates to the WP include minor
7 adjustments to the Current FY (CFY) and the following year (FY+1), center on
8 development of the FY+2 efforts for budgeting purposes, and include anticipated needs
9 for upcoming years (FY+3 and FY+4), as shown in Figure 19.

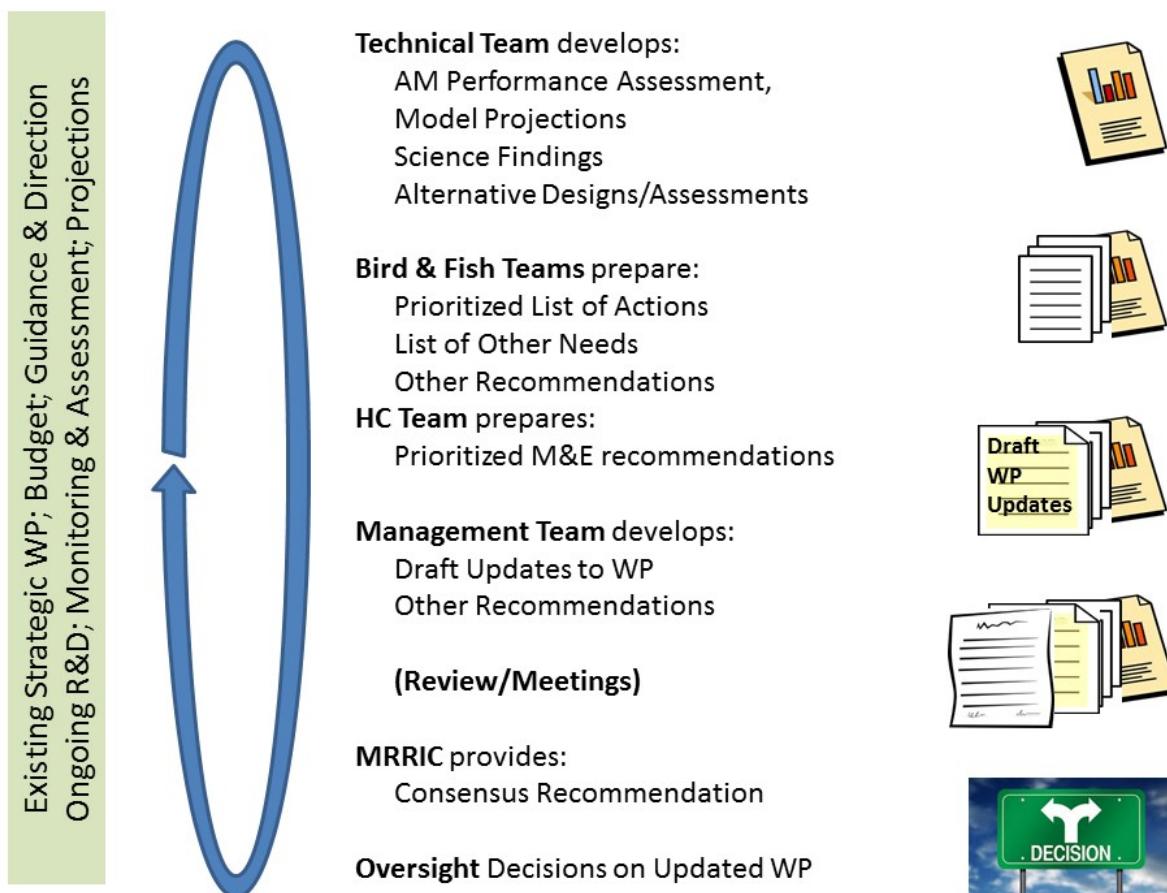

10 11 Figure 19. Schematic of the WP showing areas of emphasis for annual updates.

12 Beginning each FY, the budget appropriation for the CFY occurs between the months of
13 October and March. Following receipt of the appropriation, the WP for CFY is
14 implemented. The Draft FY+1 WP is finalized concurrently with the release of the FY+1
15 President's Budget (P-bud). Proposed projects in the FY+1 plan are organized via the
16 Project Work Request (PWR) system, which functions as a database for input of
17 proposed project information. Information on each subprogram/project is compiled for
18 input into the PWR system with all work items entered in the PWR database no later
19 than February 1 of each FY.

20 The WP update for the MRRP is focused on the Corps' development of the FY+2 budget
21 submission, which occurs from January to June of each FY. The WP update process
22 begins in earnest with the Annual AM Workshop, where the scientific findings and
23 results of data analyses from the Technical Team are assessed in terms of Program
24 implications. The WP process ends when the agencies "finalize" the updated plan in
25 June, following a series of meetings, MRRIC engagements, and an opportunity for
26 MRRIC to provide consensus recommendations on the updates. Figure 12 shows how
27 the WP update process relates to the AOP, Science Update, and MRRIC engagement
28 processes and schedules).

1 A series of important interactions occur annually as part of the WP update process
 2 (Figure 20). Information developed by the Technical Team and presented at the AM
 3 Workshop includes a performance assessment of actions implemented to date and an
 4 overall Program performance assessment, significant findings from research,
 5 monitoring and assessment, updates to the CEMs, and an assessment of hypothesis
 6 testing activities, model projections of habitat and species populations, assessments of
 7 system status, and other tasks or studies. This information is used by the Bird and Fish
 8 Teams to develop a set of prioritized actions and recommendations for each species, and
 9 by the HC Team to make recommendations regarding monitoring and assessment of HC
 10 impacts. The Teams (including the MRRIC WGs) meet separately during the AM
 11 Workshop to conduct initial discussions regarding prioritizations, then meet together in
 12 a plenary session at the end of the Workshop to share observations. The Bird, Fish, and
 13 HC Teams continue to meet as needed over the following weeks, and prepare a report of
 14 recommendations and prioritizations for submittal to the Management Team. The
 15 MRRIC WGs may prepare a separate Joint Report to MRRIC and the agencies.

17 Figure 20. Schematic of interactions occurring annually that lead to the updating of the WP.

- 1 The specific steps in the process depend on the issues under consideration (see Sections
2 2.4.5 and 2.4.6), but the overall approach remains the same each year. The Management
3 Team develops the draft updates to the WP between February and March by integrating
4 needs and recommendations of the Bird, Fish, and HC Teams and applying a
5 programmatic perspective, considering the makeup of the existing Strategic Plan,
6 guidance and direction provided by the Oversight level, budget trends, the status of the
7 science and risk management, HC effects, etc. The Management Team meets at least
8 once with agency leadership in an IPR during this period to review proposed updates.
9 The draft Revised WP is prepared in early March and is provided to the agencies and
10 MRRIC for review and comment. Proposed updates are discussed in MRRIC meetings
11 and (as needed) a webinar. Additional analyses and adjustments may be made during
12 this process depending on the feedback from agency Oversight or MRRIC. MRRIC may
13 elect to provide a consensus recommendation at their June meeting prior to the
14 agencies finalizing the adjustments to the Plan.
- 15 As part of the WP development process, the Management Team updates/determines key
16 programmatic and project resource needs, including labor (staff and contractors), and
17 materials for both the current and two upcoming FYs. This allows managers and
18 decision-makers to ensure MRRP project and programmatic activities are implemented
19 in the most efficient and effective way. The MRRP resource determination occurs each
20 year during the USACE' financial cycle and is developed in coordination with associated
21 schedules and budgets, in consultation with USACE branch chiefs. The ISP and the Bird,
22 Fish, and HC Teams are responsible for developing a resource needs with prioritizations
23 for their respective efforts. The Management Team and the ESC are responsible for
24 integrating the resource information provided by the subprogram elements into a
25 programmatic resource needs determination.
- 26 A staffing needs estimate is developed for each year concurrently with the resource
27 determinations. The Management Team develops a staffing needs summary for each
28 MRRP subprogram, working with the Bird, Fish, and HC Teams and District branch
29 chiefs. Staffing needs estimates are developed in coordination with the MRRP WP, as
30 well as associated budgets and schedules. Staffing needs estimates serve as a guide for
31 the ESC and senior leadership as resources are allocated each FY. These staffing
32 summaries are dynamic and updated as annual appropriations are finalized and
33 resources are allocated. Staffing needs summaries include provisions for staff turnover,
34 retention, and mentoring as well as a list of those contractors needed and required to
35 assist with MRRP implementation. Additionally, documentation of labor and resource
36 allocation processes includes recognition of existing institutional controls, including P2
37 and CEFMS, and is used for developing plans to address cross-district labor and
38 resource needs each FY.

1 **2.4.5 Consideration of new management actions**

2 *2.4.5.1 Triggers for the consideration of new management actions*

3 The EA identified a wide range of management actions that could be utilized to meet the
4 needs of the listed species. The MRRMP-EIS considered those actions relative to
5 program objectives and identified a subset to be applied under the MRRP as part of the
6 “first increment.” Following issuance of the ROD, the USACE will implement the
7 identified management actions, monitor their effectiveness, and develop annual
8 performance evaluations. Should those actions prove ineffective in meeting targets for
9 the listed species, the USACE, in consultation with the USFWS and with MRRIC
10 engagement will determine the appropriate course of action. That may include
11 continued implementation of the selected alternative, adjustments to the targets, or the
12 introduction of management actions other than those in the ROD.

13 If knowledge gained through research, implementation and monitoring suggests that
14 actions other than those in the ROD may be required to meet objectives, the USACE
15 should pursue investigation of alternatives for consideration as part of the WP
16 development process. The specific steps required would depend upon the circumstances
17 and the scope of additional measures under consideration (e.g., see Section 1.1.6).
18 Planning and budgeting for a change in the scope of actions under the program could
19 take considerable time and involve a high level of collaboration.

20 At present, there are no programmatic-level triggers for the introduction of new
21 management actions. The species-specific decision criteria can be applied for this
22 purpose but caution is warranted as they may not offer a sufficient basis for that
23 decision when considered in isolation. While specification of specific contingency plans
24 is not recommended at this stage, the MRRP should work toward the identification of a
25 more comprehensive suite of metrics and associated decision criteria that would define
26 the circumstances under which a decision to broaden or adjust the scope of actions
27 applied under the Program is triggered.

28 *2.4.5.2 Structured processes for decision making*

29 There will be a need under the AM Plan to make a wide range of decisions under
30 uncertainty that have complex implications for endangered species, for scientific
31 learning, for the program and for Tribes, states and stakeholders. In general, structuring
32 decision-making processes help increase transparency, efficiency, communication, and
33 accountability. In the implementation of the AM Plan, structured decision-making
34 processes should be used whenever it is clear that they would add value.

- 1 Not all decisions warrant the use of formal decision analysis; indeed, most of the
2 decisions that need to be made on an ongoing basis as part of the AM Plan will be
3 technical in nature and will not have significant or complex implications that need to be
4 analyzed in great depth. Many of the day-to-day decision-making concerning Level 1
5 and (most) Level 2 actions and associated monitoring studies will fall into this category,
6 as will the details of habitat construction designs and associated monitoring. While it is
7 true that structuring even these decisions may often help scientists think carefully about
8 the best way to approach certain issues, it is not usually necessary (nor always desirable,
9 given the additional effort required) to do so for decisions where uncertainties are low
10 and the consequences of action are uncomplicated.
- 11 Sometimes, overall decision-making complexity can be avoided through the use of
12 simple decision rules for situations for which consequences are readily understood or
13 for where the potential for a large negative consequence is low. Some of the decision
14 rules noted in Chapters 3 and 4 serve as examples. Another approach to reduce
15 complexity is to bracket-off deeper consideration of trade-offs where those
16 consequences are known to be below a pre-defined threshold (e.g., if expected impacts
17 of a decision are thought to be less than a certain amount, then analysis for an issue
18 could be neglected). In some low-stakes cases, the development of solutions to a
19 problem that are robust to external uncertainties may be preferred without need to
20 resort to deeper analysis. Robust solutions can, however, come with their own trade-offs
21 (e.g., higher cost), which might not necessarily make them the best choice, however.
- 22 Despite these examples, even seemingly quite straightforward, technical decisions can
23 suddenly become complex in the context of a large AM Plan where unintended
24 consequences could arise with insufficient thought. Decision analysis in its general sense
25 should therefore be considered as "a formulation of common sense for decision
26 problems which are too complex for informal use of common sense." (Keeney 1982,
27 806). In these cases, the diverse array of decision contexts in the plan suggests an
28 equally diverse range of decision structuring tools should be considered.
- 29 Decision structuring is already mandated by the USACE for certain situations. For
30 example, Cost Effectiveness and Incremental Cost Analysis techniques have long been
31 integral components of the USACE's water resources, environmental planning,
32 mitigation of fish and wildlife habitat losses, and ecosystem restoration. These
33 particular techniques are most helpful when there is a wide array of potential solutions,
34 when primary performance is readily quantified, and when secondary considerations
35 (e.g., effects on HC) are minor or can easily be monetized. These techniques may be
36 highly valuable for decisions related to mechanical habitat site selection questions, for
37 example.

- 1 Cost Effectiveness (CE) and Incremental Cost Analysis (ICA) become less appropriate
2 tools when cost effectiveness is not necessarily the primary driving factor in a decision;
3 when the number of options are small; when the options contain many nuanced issues;
4 and when dialog and engagement are considered a priority. In these cases, other
5 structuring tools, such as decision trees, multiple account evaluation (MAE), and multi-
6 attribute trade-off analysis (MATA) may be preferred.
- 7 There are many forms of decision analysis of this type, and numerous tools and
8 methodologies to implement them. Typically, they have in common a more-or-less
9 formal process for working through stages in decision making involving: (1) clarifying
10 the problem definition, (2) identifying issues of importance to people that might be
11 affected by the decision (objectives), (3) developing creative alternative solutions to the
12 problem, (4) estimating consequences of alternatives on objectives, and (5) evaluating
13 the trade-offs thereby exposed. This sequence of steps is sometimes referred to by the
14 acronym PrOACT.
- 15 The precise form that an analysis should take is highly dependent on the specifics of a
16 decision context. Some decision contexts will be site-level or involve a much smaller
17 scale of issues than were the case during the development of the MRRMP-EIS. During
18 that process, a consequence table decision analysis format was used to share
19 information on how the direct impacts of habitat construction or hydrological
20 differences might be felt in terms that stakeholders were familiar with, (e.g., in the
21 number of days of boat ramp availability during various seasons.). These proxy metrics
22 have the advantage of being quick to calculate from modeling and help give people a
23 sense of how one alternative might compare relative to another, but they have
24 limitations when they do not fully correlate to more complex implications, particularly
25 in an absolute sense. Later in the DEIS development, more comprehensive economic
26 calculations were performed on a smaller number of alternatives, and more precise
27 information on impacts was learned, though these calculations were intensive and took
28 months and considerable resources to complete.
- 29 Moving forward, many of the things learned from both approaches should be reviewed
30 for the suitability (or for their potential to be adapted) in support of ongoing or future
31 planning decisions. In some cases, economic models created or updated for the DEIS
32 may be updated relatively easily and, so new planning situations could best be informed
33 by re-using them. In other cases, where this approach might be too onerous, it may be
34 possible to compare the outputs of proxy metrics with economic outputs for the same
35 alternatives undertaken in the Plan in order to create response curves that may helpfully
36 approximate economic impacts.

- 1 Economic impacts are not always the best indicators for impacts, however, particularly
2 where further uncertainties are introduced to a situation through the use of assumptions
3 made to calculate them, or when they address issues (e.g., learning as an objective, or
4 issues for which NED and RED were not calculated) that may be problematic to put into
5 meaningful dollar terms. In some contexts, decision makers and stakeholders are able to
6 discuss trade-off questions more easily when impacts are left in more “natural units,”
7 constructed scales or proxy metrics (Keeney and Gregory 2005). Both approaches have
8 their strengths and weaknesses in different decision contexts, and the two can work in
9 complementary ways.
- 10 One example of this concerns the value of learning. Any changes to the management of
11 the river could have complex implications for the research programs associated with
12 Level 1 and Level 2 studies. Consideration should be given to whether and how any
13 given change could compromise the quality of information being gathered for studies; if
14 so, a judgment must be made as to whether the proposed change is worth the negative
15 impacts it might have on information quality (as one among many other things). Formal
16 academic approaches to estimating the value of information in dollar terms are
17 available, but these are problematic to apply in highly complex situations, particularly
18 when other policy objectives are being weighed.
- 19 For these reasons, and given the widely varying decision contexts that could arise under
20 the AM Plan, the USACE considers it appropriate not to detail a prescriptive process for
21 AM Plan decision making at this time. Rather, working with the HC Team, efforts will be
22 ongoing in the early stages of AM Plan implementation to explore, perhaps through the
23 use of decision scenarios or archetypes, what options might exist to present the species,
24 learning, and HC trade-offs inherent to various types of tough choices faced by decision
25 makers and stakeholders.
- 26 *2.4.5.3 Requirements*
- 27 The introduction of new management measures may require supplemental analysis
28 under NEPA if there are significant new circumstances or significant new information
29 relating to the proposed action or its impacts, even if the action were previously
30 evaluated under the MRRMP-EIS, and potentially the preparation of a new EIS (see
31 Figure 6). The essential components of an EIS are a discussion of the proposal, its
32 environmental impacts, reasonable alternatives to the proposed action and their
33 consequences, mitigation of adverse impacts, and any irreversible commitments of
34 resources.
- 35 Management actions beyond those previously evaluated under the MRRMP-EIS would
36 be subjected to the same types and degree of evaluation applied to the MRRMP-EIS. If

- 1 the new action involves flows, an update to the technical criteria in the Master Manual
2 may be required. Figure 21 is a schematic showing the update process. The process and
3 requirements are presented in detail in Attachment 5 of Appendix A.

4

11

5 Figure 21. Schematic of the process to update the Master Manual.

- 6 Expansion of this section to outline the appropriate and necessary requirements for
7 introduction of new management measures is recommended so those engaged in the
8 MRRP have a reference for the processes.

9 **2.4.6 Workflows for specific scenarios**

10 The process outlined in the previous sections provides a general overview of the
11 information flow for updating the WP. Additional details presented in this section
12 demonstrate the workflow for various types of decisions that might be needed. Decision
13 workflow examples are provided below for 10 decisions/issues:

- 14 1. Construct habitat with sufficient resources¹.
- 15 2. Construct habitat with insufficient resources.
- 16 3. Implement a test flow action included in the ROD.
- 17 4. Stop or scale back a flow action during implementation.
- 18 5. Scale up flow criteria after implementation or add a flow modification action.
- 19 6. Scale back the criteria for a flow action after implementation.

¹ This scenario includes a more detailed description of the process than is provided for other scenarios. Readers are encouraged to read this scenario first; subsequent presentations highlight the differences in the products and decision flow rather than reiterate the details of the basic process.

- 1 7. Move between pallid sturgeon action implementation levels.
- 2 8. Change species objectives, targets, or decision criteria.
- 3 9. Change monitoring and assessment associated with HCs.
- 4 10. Change the AM structure and/or process.

5
6 Many of the workflows are intended to apply generically to decisions regarding habitat
7 and flow actions for birds and/or sturgeon. For example, workflows 1 and 2 could apply
8 to constructing ESH, IRC, or both during a given year, as well as to prioritization of one
9 habitat type over the other if funding or other resources are limiting. The workflows
10 focus on specific decisions and thus do not reflect every activity that would occur in the
11 MRRP during the course of that decision. In most years, multiple decision processes
12 would be occurring at the same time. For example, annual decisions to construct habitat
13 (Scenario 1 or 2) could occur while a process to evaluate an alteration to a flow action
14 (Scenario 5 or 6), and decisions to adjust targets or decision criteria (Scenario 8) are
15 also be ongoing.

16 Which workflows apply to a given decision cycle is in itself a decision (e.g., whether to
17 implement flow releases or use construction to create habitat. Typically, information
18 developed during the Evaluate step of the AM cycle indicates which process will need to
19 be followed. Criteria for these decisions are included in the species management
20 chapters in Sections 3.4 and 4.3.

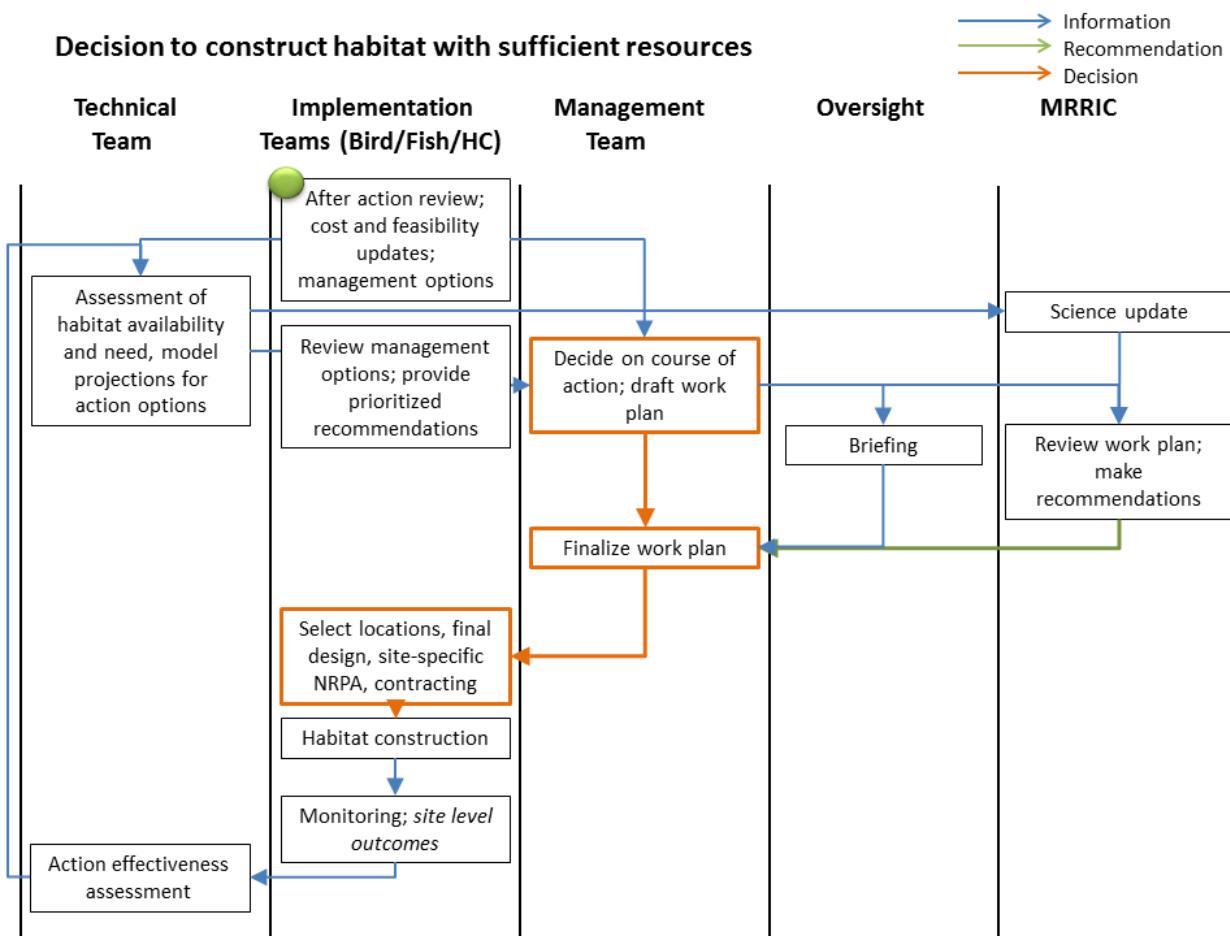

21 The time frame for decisions is variable. Some processes take place within the WP
22 update cycle, which recurs annually, although the process of moving from evaluation to
23 decision to implementation typically takes 2 years or longer. Other scenarios, such as
24 changes to species objectives or targets, are infrequent and can be addressed at any time
25 through the normal engagement/collaborative process. Various decisions can take more
26 or less time depending upon the level of supporting analyses, NEPA processes, and
27 collaboration required for the decision.

28 Draft timelines have been created for scenarios 1–4 based on the annual WP
29 development cycle described in Section 2.4.4. They indicate, through shading, processes
30 described in the workflows for each level. Arrows indicate the transmission of
31 information (no marker), recommendations (marked by ♦), and decisions (marked by
32 ◆) between levels. As with the workflows, the timelines do not show all concurrent
33 activities but rather those for a single decision workflow. Typically the decision cycle
34 takes 1 year for these scenarios, with implementation of the planned action taking place
35 2 to 3 years after initiation of the decision process. In practice, another decision cycle
36 would occur during the year of implementation. These timelines will continue to be
37 developed and used to evaluate whether sufficient time is available for review,

- 1 collaboration, and approval processes. Dates shown in the timeline are provisional and
- 2 subject to revision.

Note: Independent panels, states and tribes acting in roles other than MRRIC, and the public are not represented in these diagrams. Similarly, information development, studies, preliminary engineering and design, site-specific environmental assessments and other interactions internal to the agencies are not shown. These needs vary from issue to issue and are left to the agencies to address as needed.

- 3 2.4.6.1 *Decision to construct habitat with sufficient resources*
- 4 Scenario 1 (Figure 22) describes the process for implementing habitat construction
- 5 when there are sufficient resources to conduct the desired actions to their full extent.
- 6 This decision process would also apply to habitat modification and other non-flow
- 7 actions for which budget and staffing resources must be allocated but water operations
- 8 are unaffected. The workflow begins following previous implementation of actions
- 9 under this AM Plan (i.e., in Year 2 or later of implementation).
- 10 At the start of the Evaluate stage of the AM cycle, the Bird and Fish Teams meet
- 11 (typically in conjunction with the Fall Science Meeting) to review the previous FY's
- 12 activities and the needs for the current and upcoming year, as well as the projected
- 13 budget and AOP. Using the most current information and estimates (e.g., habitat needs
- 14 projections, decision criteria and contingency plans, prioritized list of projects carried
- 15 over from last year, cost estimates for projects and cost per unit estimates, feasible
- 16 implementation extent, notable constraints on implementation due to site or contractor
- 17 availability, etc.,), they identify a preliminary set of alternatives and issues related to the
- 18 WP. They provide this information to the Technical and Management teams, along with
- 19 a list of analytical needs/studies to be undertaken by the Technical Team. Concurrently,
- 20 the HC Team meets to review monitoring and assessment results related to HC
- 21 interests, and to consider whether any changes are needed. They provide any
- 22 recommendations for changes to monitoring and assessment to the Management Team.
- 23 The Technical Team uses information from monitoring and research programs to
- 24 prepare an updated assessment of the habitat and population status, review the
- 25 hypotheses, CEMs, and predictive models, and evaluate the effectiveness of previously
- 26 implemented actions and the Program on the habitat and species, and to assess any
- 27 impacts on HC interests. A draft report is prepared by the Team, which is provided prior
- 28 to and presented during the Annual AM Workshop (see Section 2.4.3).

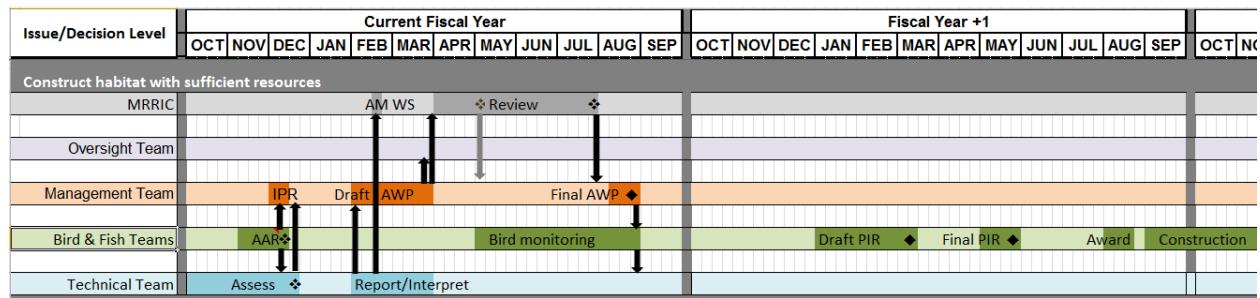

1

2 Figure 22. Workflow for decision to construct habitat with sufficient resources.

- 3 The Technical Team and/or District planning and engineering PDT uses the information
4 about system status together with the cost and feasibility information (see Section
5 2.5.13) to evaluate a range of management options. This includes development of
6 feasibility-level plans and preliminary designs for new projects as requested by the Bird
7 and Fish Teams as well as experimental designs for innovative management actions to
8 be tested at Level 2. Potential management actions should be evaluated using predictive
9 numerical models to the fullest extent possible. Model projections should include at
10 least one management option that will meet the objectives, a “do-nothing” option for
11 baseline comparison, and in most cases, at least one alternative.
- 12 The Technical Team provides a summary report of their findings, and the District PDT
13 provides preliminary siting, design, and cost information for the management options,
14 along with a summary of related findings to the Implementation and Management
15 Teams. The Technical Team’s reports are presented at the Annual AM Workshop.
16 During the presentation, attendees may question presenters on the analyses, the

- 1 implications of any new findings, etc., and conduct discussions of the relevance of
- 2 lessons learned to the Program.
- 3 Following the AM Workshop, the Bird and Fish Teams use the information from
- 4 workshop discussions and the reports provided by the Technical Team together with
- 5 information on budget, staffing, and other resources to develop a prioritized set of
- 6 management actions, research priorities, and recommendations regarding the following
- 7 year's AM Plan for each species. They may also develop recommendations regarding
- 8 other Program needs (e.g., elevating a reserve hypothesis, or changing a component of
- 9 the AM Plan). Their recommendations, in the form of a report, are provided to the
- 10 Management Team, as are the HC Team's recommendations regarding needed
- 11 monitoring and assessment. The MRRIC Bird, Fish HC WGs prepare an additional
- 12 report with their observations and recommendations and may, at their discretion,
- 13 present them to the Management Team. This occurs in the initial step of the
- 14 Adjust/Continue step of the AM cycle.
- 15 The Management Team meets to discuss the Program's WP. They consider the
- 16 prioritizations and other input from the Bird, Fish, and HC Teams, along with the other
- 17 factors previously listed, and merge the proposals into a draft of the WP. The Draft WP
- 18 and any recommendations from the Management Team are added to those of the
- 19 individual Implementation Team requests and provided to the Oversight Team and to
- 20 MRRIC for consideration at the Spring MRRIC Meeting.
- 21 The information generated during the Science Update and WP development processes
- 22 are retained in a "chain of custody" such that it is clear how information was used to
- 23 support decisions and where decisions deviate from the recommendations of other
- 24 Teams. The recommendations of the Management Team, along with the underpinning
- 25 information and products, are presented at the Spring MRRIC meeting for
- 26 consideration. If the recommendation meets all objectives within the available
- 27 resources, there will typically be little need for discussion of the proposed alternative,
- 28 though other recommendations may demand dialogue. MRRIC has the opportunity to
- 29 make recommendations prior to finalization of the WP. The decision to approve the
- 30 proposed WP or to approve it subject to certain alterations or other provisions is made
- 31 by the Division Commander.
- 32 The Management Team receives guidance and direction from the Commander, and the
- 33 ESC provides direction on resource availability for particular actions, and, when
- 34 appropriate, allocation to geographic area (e.g., ESH construction allocation for
- 35 Garrison and Gavins Point reaches) or other provisions. The District PDTs conduct the
- 36 necessary assessments, finalize designs and cost estimates, and prepare needed

- 1 information for contracting. Related decisions will be confirmed by the Management
 2 Team following finalization of the WP and any adjustments required to accommodate
 3 current conditions on the ground. Adjustments to methodologies or design of projects
 4 based upon learning from previous implementation may also occur at this stage. Any
 5 conflicts that cannot be resolved will be addressed by the conflict resolution process (see
 6 Section 2.5.1). This concludes the Adjust/Continue decision step.
- 7 The ISP is responsible for providing scientific guidance and support to the Bird, Fish,
 8 and HC Teams regarding the application of science to implementation of construction or
 9 modification projects and is directly responsible for monitoring of project outcomes as
 10 necessary, as well as for species and habitat monitoring. These outcomes are carried into
 11 the Evaluate step, and the decision process is repeated.
- 12 The timeline for this workflow is shown in Figure 23 for the example of ESH
 13 construction. A similar decision process would occur for pallid sturgeon habitat (IRC or
 14 spawning) construction, though the timing of planning and implementation may differ.
 15 The timeline illustrates the time allotted for creating, reviewing, and finalizing the WP
 16 beginning with the after -action review from the Bird, Fish, and HC Teams and initial
 17 assessment and the draft report from the Technical Team at the Fall Science meeting. A
 18 4-month review period for MRRIC is included prior to the finalization of the WP. The
 19 time lag between the initial assessment of monitoring information by the Technical
 20 Team and the construction of habitat is roughly 2 years.

22 Figure 23. Timeline for decision to construct ESH¹ with sufficient resources.

23 Note that while the decision process is carried out annually and concurrently with the
 24 implementation of the previous year's decisions, evaluation and decision making is
 25 forward-looking to the extent possible given natural system variability and potential
 26 budget fluctuation. The nature of the decision process is influenced by the projected
 27 budget and the risk of a budget shortfall (or plus-up). Thus, feasibility assessments,

¹ Process is the same for IRCS, but the timeframe may shift slightly.

1 model projections, and management-level decisions are based upon on a 1–3 year
2 budget horizon with the understanding that some adjustments may be made to
3 accommodate current-year system state (e.g., storage, habitat availability, population
4 trends). This scenario provides the foundational decision-making process upon which
5 more complex implementation decisions are based. Information flow among the
6 Technical Team, Bird/Fish Teams, Management Team, Oversight, and MRRIC for the
7 general scenario is shown in matrix form in Figure 24. The matrix will be updated to
8 reflect pending changes in the composition of WGs and AM Teams and to include added
9 detail regarding products and information flow. The following sections primarily
10 describe deviations from this workflow to accommodate different or additional
11 decisions, and may involve additional information and other entities.

1 2.4.6.2 *Decision to construct habitat with insufficient resources*

2 In some years, insufficient resources (budget, staff, implementation capacity) may be
3 available to conduct all activities considered necessary to have sufficient likelihood of
4 meeting habitat and population objectives. If it has been decided that other options such
5 as flow modification to create habitat are not available, a decision must be made on the
6 allocation of resources with the knowledge that some objectives may not be met. This
7 may require prioritization of one species or one geographic region and subpopulation
8 over another. These decisions may require greater information about management
9 options. Because compliance with ESA requirements may be in question if objectives are
10 not met, decisions about actions are elevated to the Oversight level.

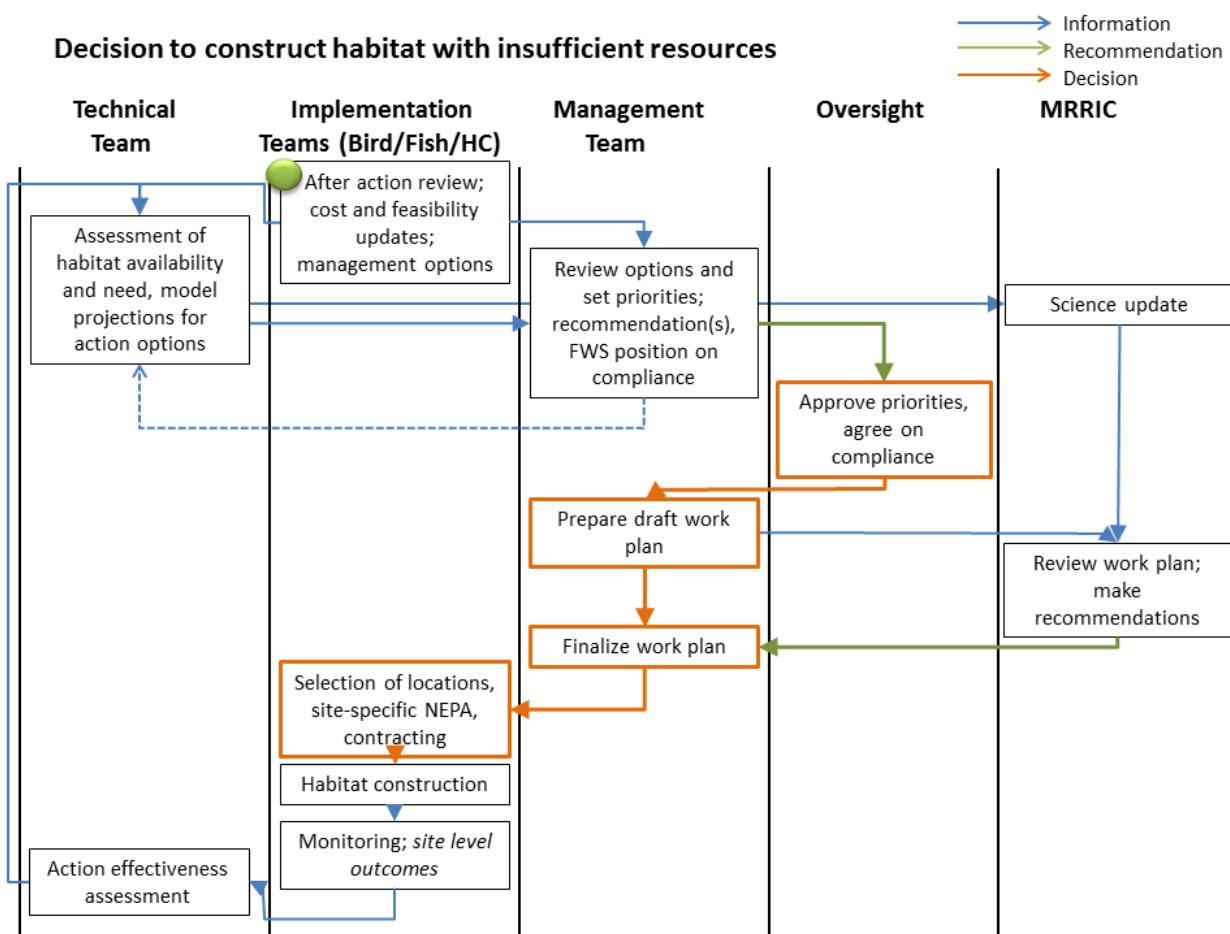

11 The process (Figure 25) begins in the same manner as Scenario 1 with the provision of
12 cost and feasibility estimates by the Bird and Fish Teams and science and management
13 option assessments and evaluation by the Technical Team, and the Science Update
14 process. Even if it is clear that resources will be insufficient to meet all objectives, the
15 Technical Team will identify an option that does meet all objectives to identify the
16 bounds of the decision space. As this information is provided to the Management team,
17 there may be a need to evaluate additional management options not originally
18 considered in order to find an optimal management pathway. The workflow
19 accommodates an iterative process with the Management and Technical (and, if needed,
20 Bird and Fish Teams) to develop management options. This process requires some
21 additional time that must be accommodated in the overall schedule.

22 Following evaluation, the Management Team recommends a management option, with
23 justification for the selection and prioritizations included. The USFWS members of the
24 Management Team prepare a draft position on the impacts of the management decision
25 on compliance with ESA or other requirements if objectives for all species are not
26 expected to be met. Because of the potential effects on compliance at the policy level,
27 Oversight must decide to approve the recommendation or choose an alternate option,
28 and may need to address any conflicts of interest that arise within the Management
29 Team from decisions that impact their near-term funding. The Oversight decision
30 makers will serve as arbiters of any disagreement that cannot be resolved within the
31 Management Team.

32 If long-term budget outlooks suggest that insufficient resources to meet objectives will
33 be ongoing in the moderate to long term, the process to request higher levels of funding
34 in the future and/or to adjust program expectations would be required.

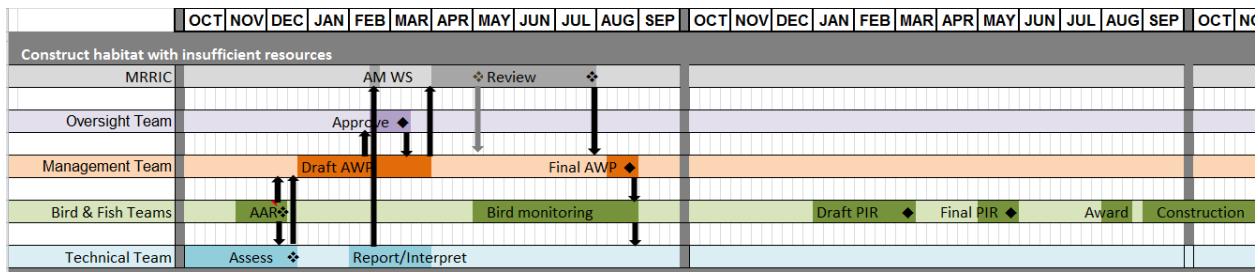

- 1 Following Oversight level approval (or adjustment) of the Management Team's
 2 recommendations, the draft WP is developed, and the process continues as described for
 3 Scenario 1.
- 4 The timeline for this scenario (Figure 26) is very similar to the previous scenario, with
 5 the exception of a greater amount of time needed for the Oversight level to review and
 6 approve the draft WP. This review window compels an earlier initiation of the WP
 7 drafting process. The initial assessments shared in the fall IPR (see Section 2.4.3) would
 8 need to determine the likelihood of need for Oversight review to approve prioritization
 9 decisions.

10

11
 12 Figure 25. Workflow for decision to construct habitat with insufficient resources.

13

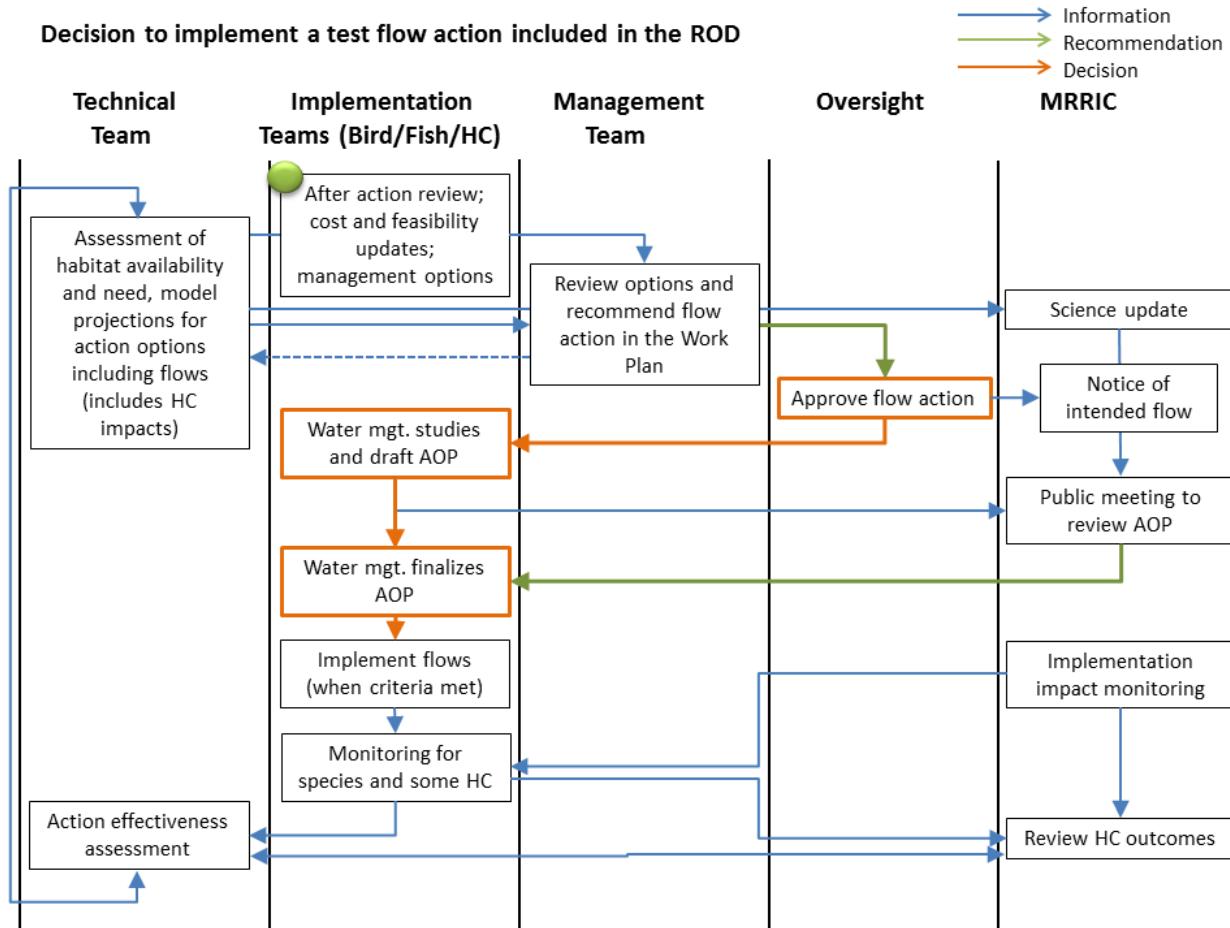

2 Figure 26. Timeline for decision to construct habitat with insufficient resources.

3 2.4.6.3 Decision to implement a flow action included in the selected alternative after the
4 ROD

5 In some decision cycles (Figure 27), flow releases to create habitat or spawning cues
6 may be an option (see Section 3.6.1). In many cases, the need for flows will arise as part
7 of moderate-term planning and be identified as a management option prior to the
8 Evaluate step in a given year. In others, the need may be identified by the Technical or
9 Bird Team during that decision cycle's assessments. In either case, the Technical Team
10 evaluates both flow modification management as well as non-flow options.

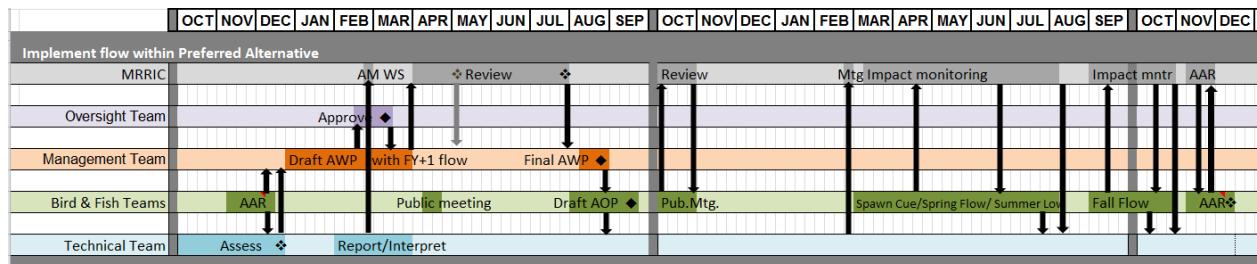

11 If the Bird Team includes a flow action in their list of prioritized recommendations, they
12 notify MRBWMD, who ensures their representative on the Management Team
13 addresses the viability of a flow modification option during the Team's deliberations. If
14 the Management Team recommends that option in the draft WP, the MRBWMD
15 provides input at the Oversight level regarding a decision to implement. If approved as
16 part of the WP and if that flow option was included in the ROD and updated Master
17 Manual and the other criteria are met (e.g., system storage, etc.,) then it can be included
18 in MRBWMD's planning and AOP process (see Section 2.4.2.1). If the recommended
19 flow modification was not included in the ROD or was not addressed in the Master
20 Manual, a different decision path would be required (see Section 2.4.6.5).

21 Note that, even if approved and included in the WP, actual implementation of the flow
22 action would not occur unless and until the criteria for that action were met. During the
23 implementation step, monitoring will occur to evaluate HC metrics as well as flow
24 effects on habitat and/or species outcomes (see Sections 3.3.1, 3.3.5, and 3.3.6). This
25 may include formal or informal impact monitoring and reporting by members of
26 MRRIC or external partners. After-action assessment will include a review of
27 habitat/species and HC outcomes with MRRIC (see Section 3.5).

2 Figure 27. Workflow for decision to implement a flow action.

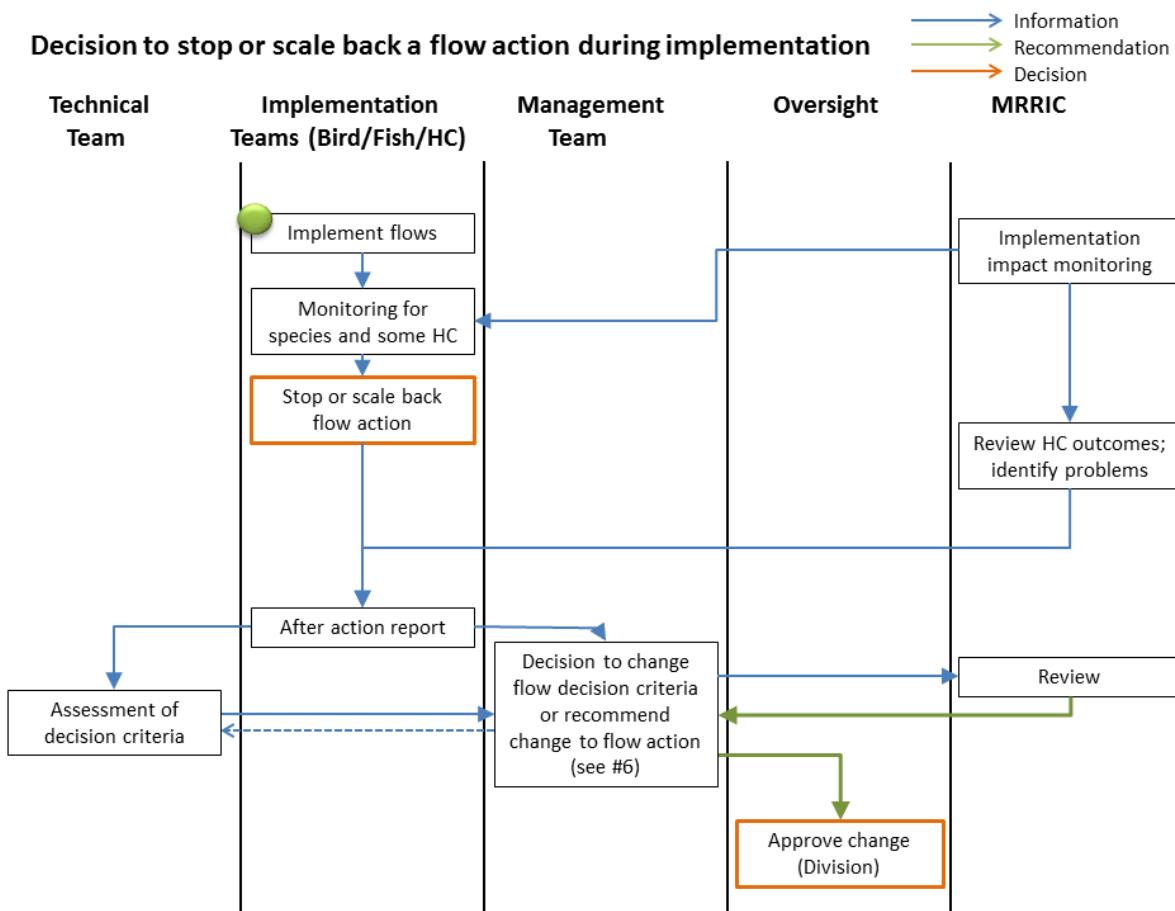

3 The timeline for this scenario (Figure 28) is similar to the timeline for constructing
 4 habitat with insufficient resources, as it also requires Oversight level approval of the
 5 decision to implement a flow in the following FY. The activities of the Bird, Fish, and HC
 6 Teams reflect the process of working with Water Management to draft and provide for
 7 public review the AOP that would include the planned flow. The timing of the flow
 8 depends on the type of action being carried out; a broad window allowing for several
 9 potential flow scenarios is included. During the flows, information about forecasts,
 10 changes to flows, and any observed impacts are shared between the Implementation
 11 level and MRRIC. Following the flow, MRRIC has the opportunity to participate in an
 12 after-action review to provide feedback on the flow implementation to the agencies.
 13 Formal recommendations from MRRIC, if desired, would follow that process.

2 Figure 28. Timeline for decisions to implement a flow action.

3 2.4.6.4 Decision to stop or scale back a flow action during implementation

4 If a test flow is implemented under the ROD, or if flow actions are added to the MRRP at
 5 some future point, flow modification actions may be halted during implementation.
 6 Unacceptable HC or habitat/species impact may trigger modifications of planned
 7 releases or returns to routine flow operations, for example. Actions may also stop early if
 8 monitoring indicates desired effects (objectives of the flow action) have already occurred
 9 and no further action is needed.

11 Figure 29. Workflow for decision to stop or scale back a flow action.

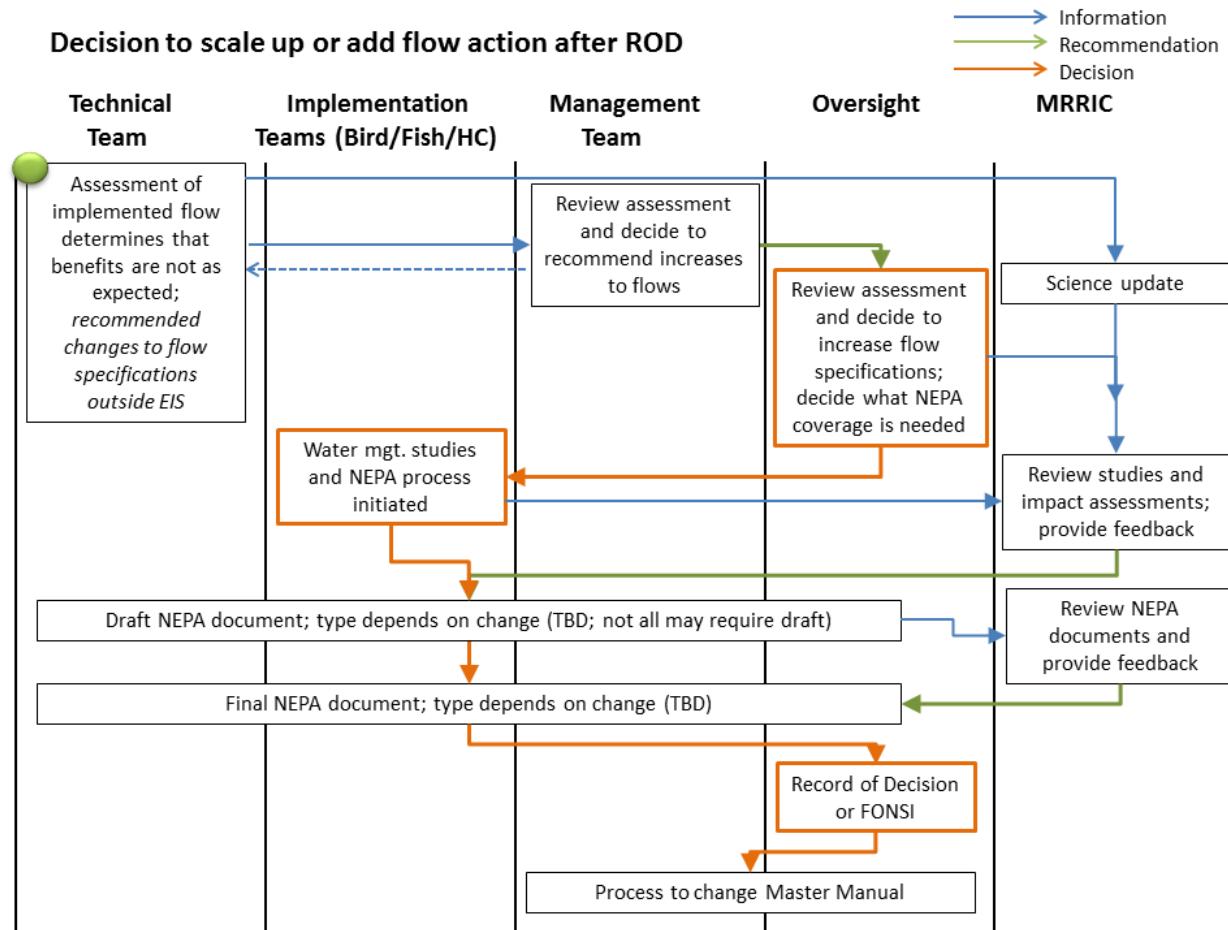

1 This decision pathway is triggered by impact monitoring to HC or species/habitat as
2 described in Section 2.4.6.3, based upon decision criteria specified in advance for any
3 approved flow modification (e.g., Section 4.2.1.3). If flows are stopped or scaled back,
4 the after-action assessment includes an evaluation of what occurred to trigger the
5 adjustment, why it occurred, and if changes would be necessary to prevent repetition of
6 any adverse outcome. Note that in most cases, decision criteria should trigger a
7 cessation or adjustment of the flow prior to actual impacts occurring. MRBWMD would
8 implement the flows in accordance with the criteria in the MM and would make the
9 decision to stop or scale back the flow option based on that criteria listed in the MM.
10 The assessment will determine whether or not negative impacts occurred and whether
11 the abbreviated flow had beneficial outcomes.

12 The Technical and Bird, Fish, and HC Teams provide these assessments to the
13 Management Team, which considers whether changes should be made to decision
14 criteria and/or the specification of the flow modification itself. If a change is warranted,
15 they craft a recommendation to the appropriate Oversight leadership. The process to
16 make these changes, including MRRIC collaboration, is described in scenario 7.

17 *2.4.6.5 Decision to scale up flow criteria or add a flow modification action*

18 Decisions to add a new flow modification or change the specifications of an existing flow
19 modification to increase the frequency, duration, or magnitude of deviation from
20 routine reservoir operations require a reformulation process (Figure 30). This process is
21 initiated if the assessment of implemented flows by the Technical Team determines that
22 the benefits of the existing flow were not sufficient AND that the HC impacts have not
23 been unacceptable and that there is room to expand the definition of the flow action
24 without causing unacceptable impacts. Upon reviewing the assessment, the
25 Management Team can decide to pursue an adjustment to the flow action through a
26 recommendation to the Oversight Team.

27 An Oversight decision to approve the recommendation initiates the process to change a
28 flow specification. The nature of the process depends on whether the flow action has
29 been previously evaluated in an EIS, included in the ROD, or in the Master Manual (see
30 Figure 6). If the action was not evaluated in the EIS, or the analysis is no longer
31 adequate, then an additional NEPA process will be required, and an adjustment to the
32 Master Manual required (Attachment 5). If the action was evaluated in the EIS and the
33 analysis is still adequate, but the action was not part of the selected alternative described
34 in the ROD, an additional decision document will be required. If the action is not
35 included in the Master Manual, the process to include it will then be followed.

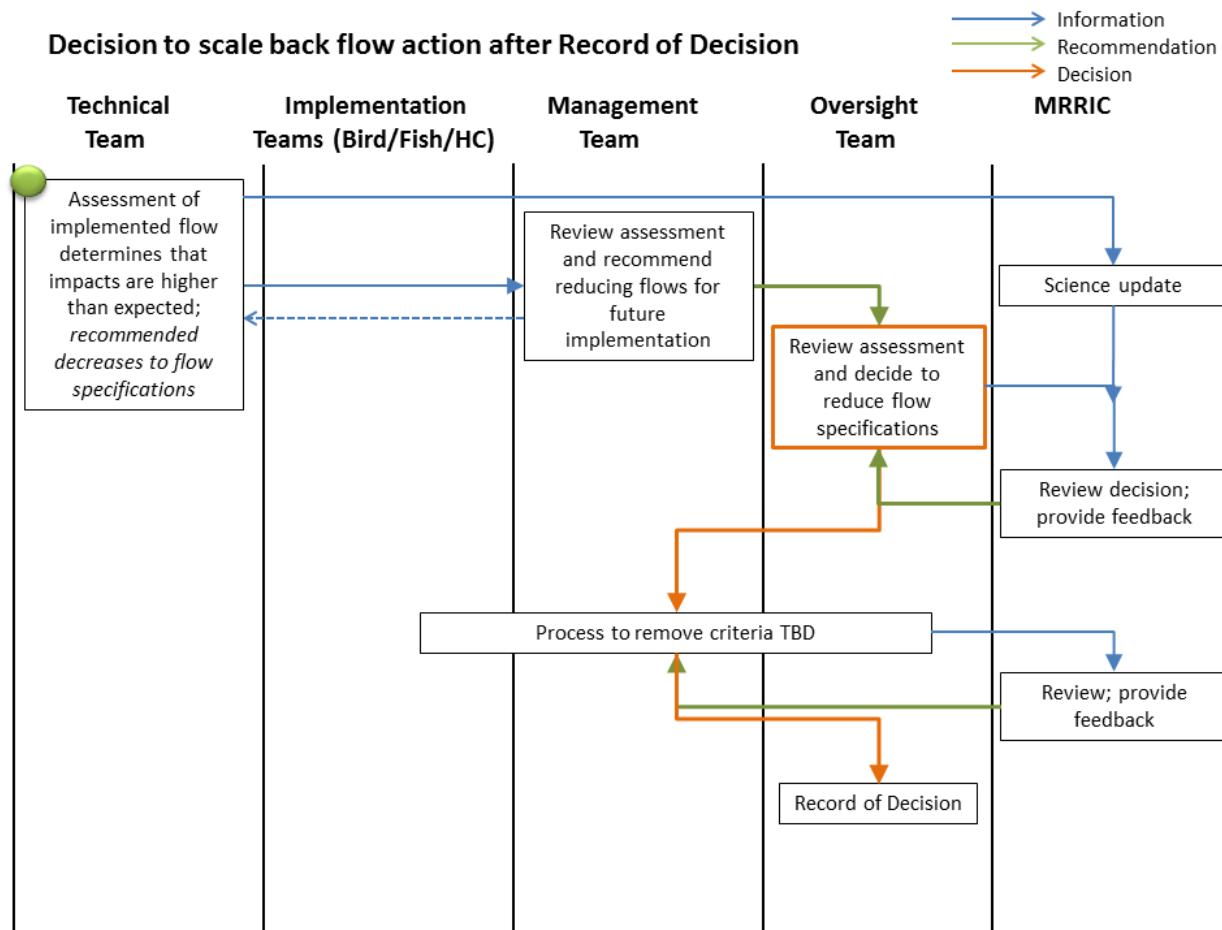

2 Figure 30. Workflow for decision to add or change a flow action.

3 Note: The specific processes to conduct additional NEPA analysis,
4 produce a new decision document, and/or alter the Master Manual are
5 not described in the draft AM Plan, but will be incorporated into the final
AM Plan.

6 2.4.6.6 Decision to scale back the criteria for a flow action after the ROD

7 If the post-implementation assessment of a flow action determines that adverse impacts
8 are unacceptable, or would have been unacceptable had the flow action not be
9 terminated early, the Management Team can recommend that the specifications of the
10 flow action be reduced in duration or magnitude to create a lesser deviation from
11 routine operations in future implementation of the action. The decision at the Oversight
12 level initiates the process to change the flow criteria and produce a new decision
13 document in collaboration with MRRIC and partner agencies (details to be determined).
14 As these changes result in actions of lesser extent than previously evaluated in the EIS

1 or subsequent NEPA analysis, they will not require additional assessment under that
 2 process. (Cases where a decrease in one criterion [e.g., flow magnitude], is offset by
 3 other criteria such as duration or frequency would be considered a modification under
 4 the previous example and may require additional coverage.)

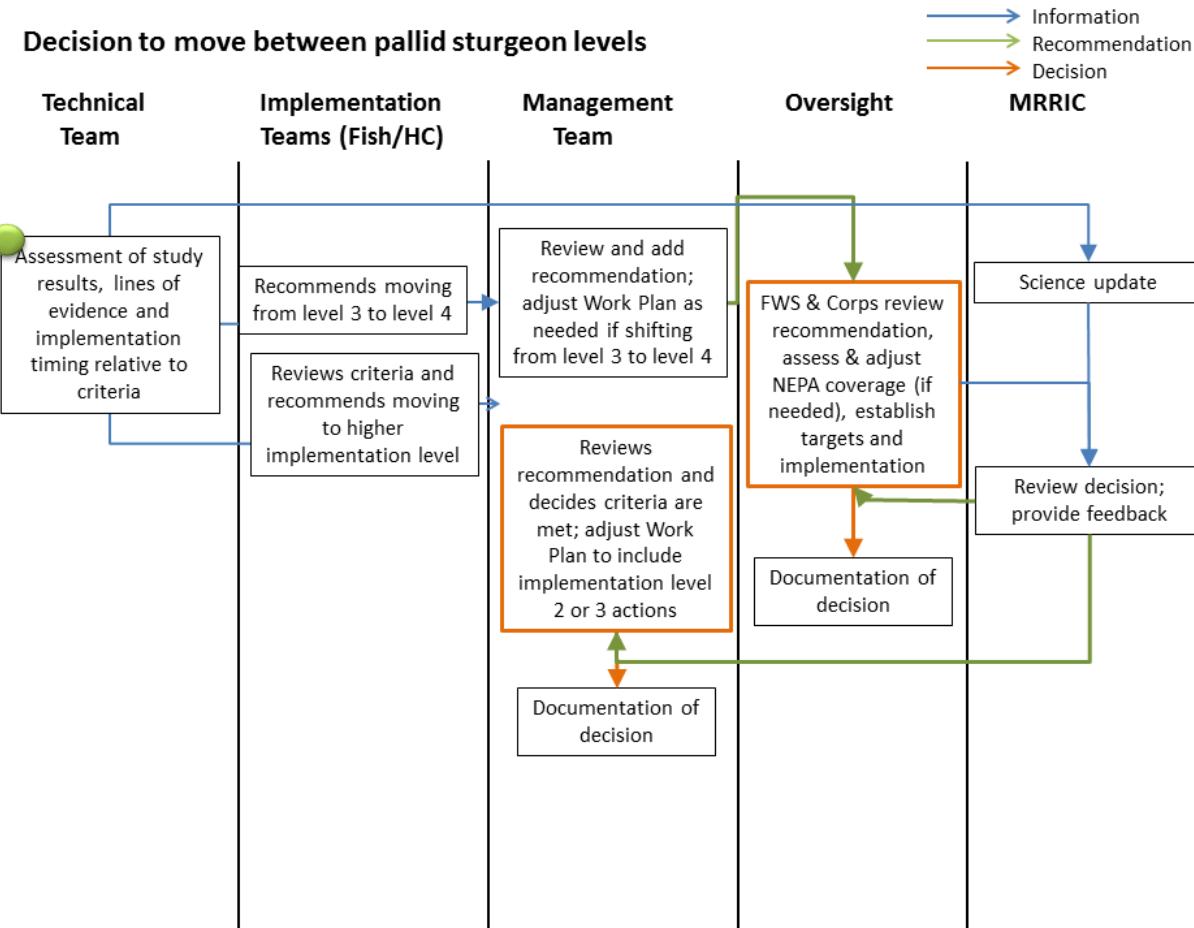

5
 6 Figure 31. Workflow for decision to scale back a flow action after the ROD.

7 2.4.6.7 *Decision to move between pallid sturgeon implementation levels*

8 The workflow shown in Figure 32 summarizes the process to change between
 9 implementation levels for pallid sturgeon management actions. Variations on this
 10 workflow may occur depending on the trigger for the change, which could be based on
 11 (1) the assessment of Level 1 and 2 study results that are sufficient to reject a null
 12 hypothesis, (2) results of the lines of evidence assessment procedure (see Section 4.2.1),
 13 and (3) in accordance with the decision criteria for timing of Level 3 and/or Level 4
 14 actions (see Section 4.2.1). These assessments occur annually and are communicated as
 15 part of the Science Update process (see Section 2.4.3). The Fish Team reviews findings
 16 and recommendations from the Technical Team and decides whether a move from Level

1 1 to Level 2, or from Level 2 to Level 3, is merited, and provides documentation of the
 2 basis for their recommendation. Recommendations of the Fish Team are reviewed by
 3 the Management Team, which makes its own recommendations and adjustments to the
 4 draft WP for consideration at the Oversight level. If the decision to move to Level 4 is
 5 made, Oversight must also approve targets and document the decisions and supporting
 6 material. If this process results in changes to flow actions, changes are made following
 7 the processes outlined in Section 2.4.6.5.

8

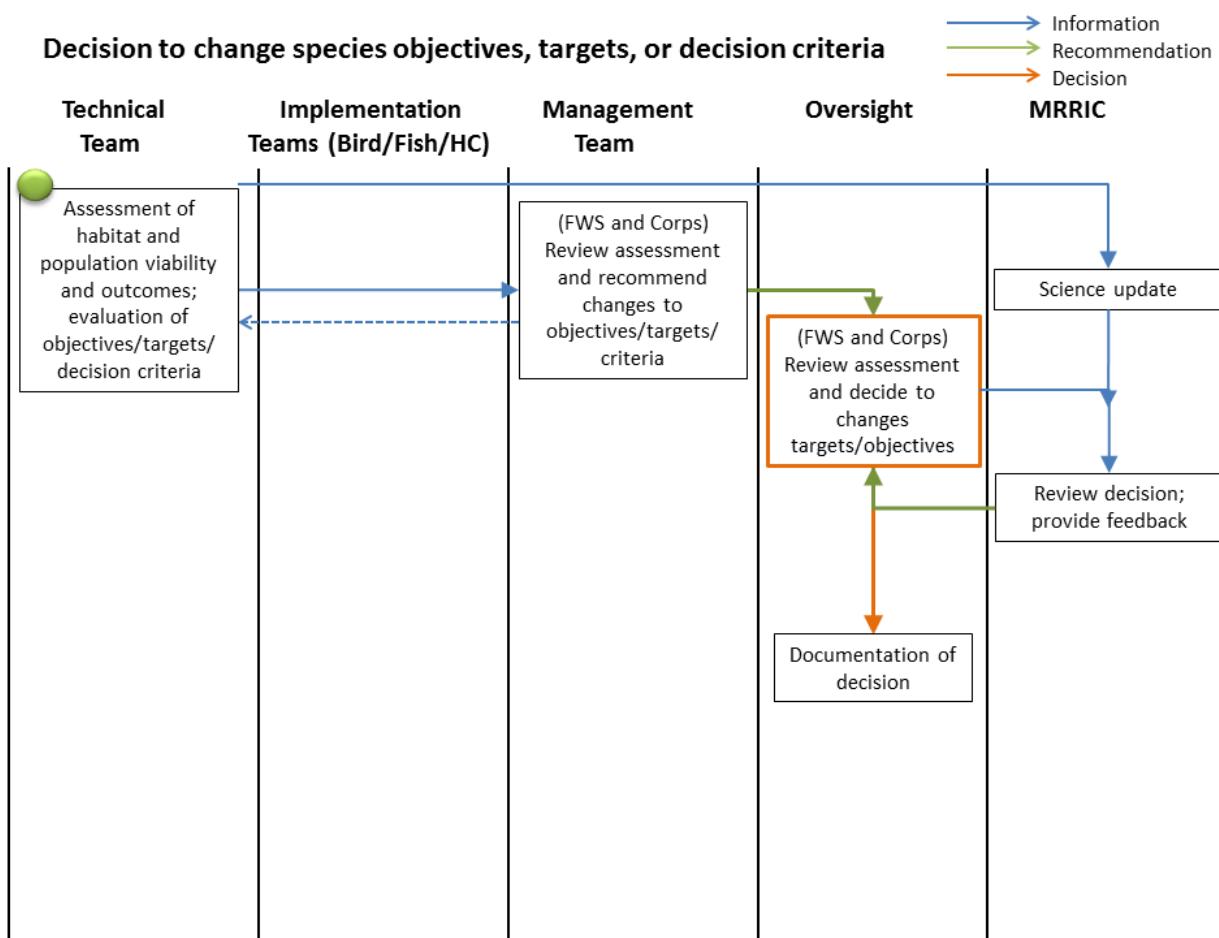

9 Figure 32. Workflow for decision to move between pallid sturgeon implementation levels.

10 2.4.6.8 *Decision to change species objectives, targets, or decision criteria*

11 A decision to change species objectives, targets, or decision criteria may be initiated in
 12 several ways:

- 13 • Evaluation by the Technical Team determines that targets or criteria are no longer
 14 sufficient to meet habitat, species, or program objectives, either as a result of
 15 increased system understanding or fundamental changes to the system. They may

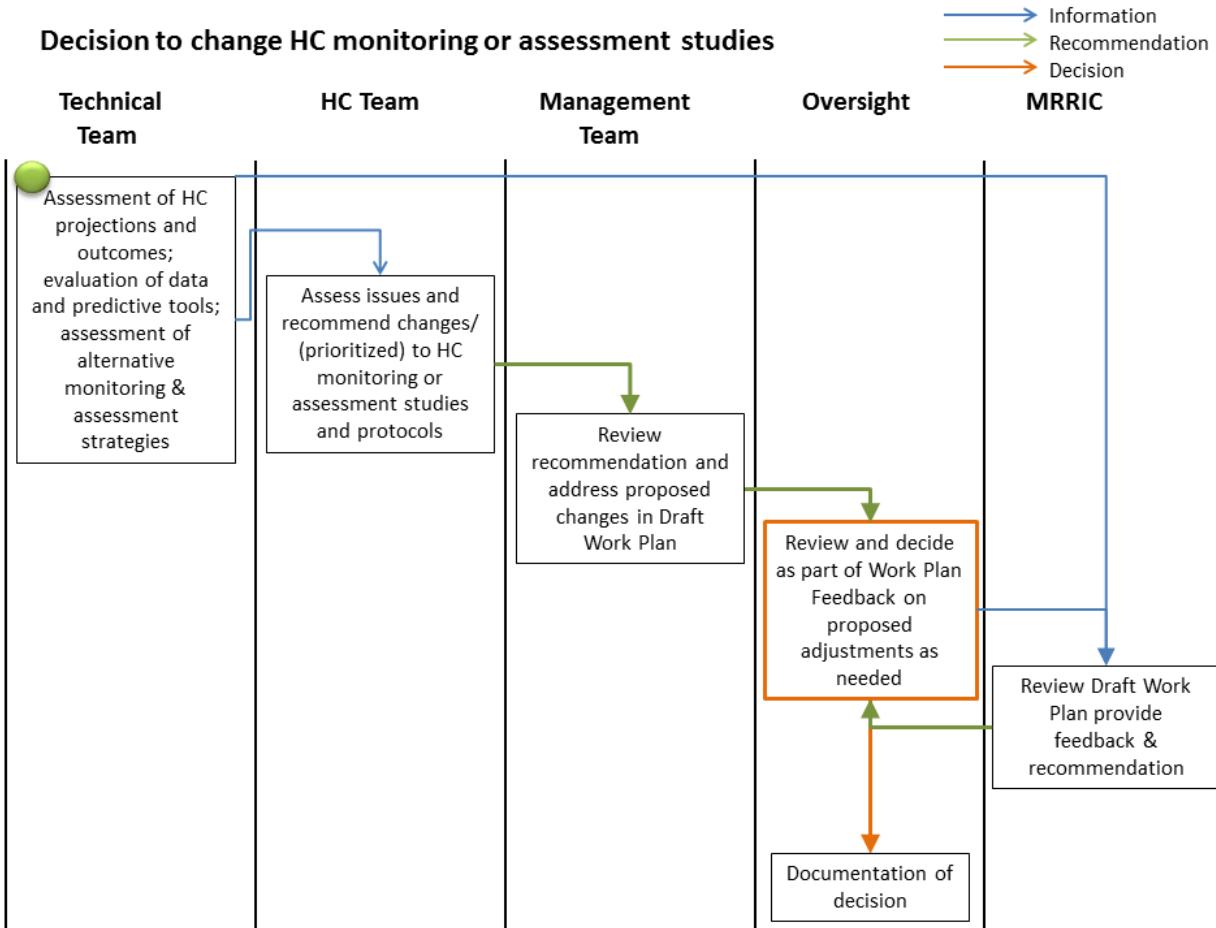

- 1 recommend new targets or criteria as part of the Science Update process and in the
 2 report to the Management Team.
- 3 • MRRIC may make a recommendation to reevaluate objectives, targets, or criteria
 4 including the consideration of adding or removing objectives or criteria. They may
 5 also request evaluation from Panel resulting in recommendations.
- 6 • Oversight level leadership may request reevaluation of objectives, targets, or criteria,
 7 including changes driven by national or regional/divisional changes in regulations,
 8 authorities, or other policies.
- 9 In the latter two cases, reevaluation will be performed by the Technical Team and draft
 10 findings shared through the Science Update or similar process. Depending on the type
 11 and magnitude of the change, additional collaboration with MRRIC and/or other
 12 partners may be initiated. Final decisions on these changes are made at the Oversight
 13 Level and recorded and communicated through a decision document.

14

15 Figure 33. Workflow for decision to change species objectives, targets or decision criteria.

- 1 2.4.6.9 *Decision to change monitoring or assessment needs for HCs*
- 2 A recommendation to change aspects of the monitoring and assessment of HCs in support of the AM process may be initiated by the HC Team if existing data are found to be inadequate, if ongoing studies are no longer required, or if current practices are inefficient or ineffective. HC monitoring and assessment needs will be considered annually by the HC Team as part of the science update and annual WP development processes. Periodic programmatic reviews will also be conducted and may result in findings that include recommendations for any needed changes to HC monitoring and assessment. Protocols for addressing changes are similar to those for any other component of the AM Plan and the workflow is as shown in Figure 34. Because changes to HC monitoring and assessment are generally considered as part of the WP process, although needs will generally be addressed as part of the Science Update Process. The degree of collaboration and time required to make a change will depend on the change itself as well as the available budget; however, decisions can generally be made within the year they are introduced and can be implemented as soon as the following year.
- 3 MRRIC may provide a consensus recommendation on the suggested course of action.
- 4 The AM expertise on the Technical Team may provide assistance to the HC Team and advise changes, and/or draw insights or guidance from other AM programs as beneficial. Final approval of any recommended changes resides at the Oversight Level.
- 5 Changes are communicated through a summary decision document, usually as part of the approved WP, and revisions are made to the AM Plan (as needed).

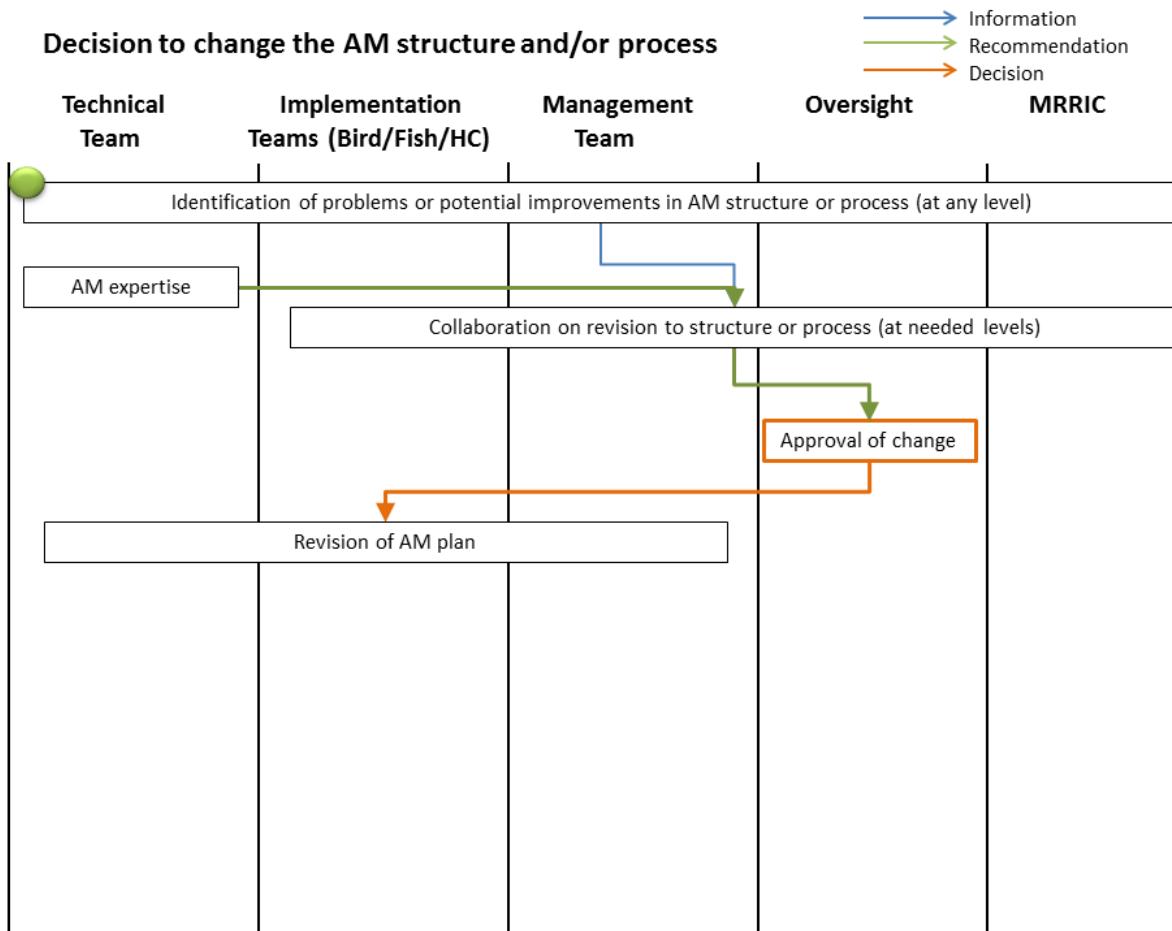

2 Figure 34. Workflow for decision to change monitoring or assessment needs for HCs.

3 2.4.6.10 *Decision to change the AM governance structure and/or process*

4 A recommendation to change aspects of the AM process may be initiated at any level if
 5 communication, collaboration, decision-making, or other components of the process are
 6 found to be inadequate or inefficient. A periodic programmatic review will also be
 7 conducted with findings documented and include recommendations for any needed
 8 changes. Protocols for changing significant components of the AM Plan are provided in
 9 Attachment 6 of Appendix A. The degree of collaboration and time required to make a
 10 change will depend on the change itself; (e.g., reorganization of the Management Team
 11 can primarily be handled at that level; reorganization of the MRRIC collaboration
 12 process may require collaboration between MRRIC and multiple governance levels
 13 within the agencies, and preferably MRRIC consensus on the recommended course of
 14 action). The AM expertise on the Technical Team may provide recommendations and
 15 advise changes, and/or draw insights or guidance from other AM programs as
 16 beneficial. Final approval of any recommended changes resides at the Oversight Level.

- 1 Changes are communicated through a summary decision document and revision to the
 2 AM Plan.

- 4 Figure 35. Workflow for decision to change the AM structure and/or process.

5 **2.5 Important protocols and procedures**

- 6 This section lists and summarizes a number of activities critical to the program's
 7 execution and governance. Protocols or procedures for these activities, as needed, are
 8 included as attachments to Appendix A.

Note: Details of some processes in this section are under development. Additional process descriptions may be identified and descriptions of listed processes and procedures updated and reviewed for the final AM Plan.

1 **2.5.1 Procedures for dispute resolution**

- 2 Given the large number of considerations and decisions to be addressed in executing the
3 MRRP, disputes are inevitable. A commitment to the rapid and transparent resolution
4 of disputes/ conflicts is required from all parties and clear processes are needed to
5 achieve resolution of those concerns. The approach for resolving conflicts within the
6 MRRP depends on the nature of the conflict (technical or policy consideration) and the
7 parties involved. The ultimate authority for resolving conflict lies with the agency
8 leadership, but every effort should be made to resolve conflicts at lower levels.
- 9 For disputes within a lead agency, In-Progress Review (IPR) meetings provide
10 opportunities to resolve issues and differences of opinion regarding selection of
11 management actions and/or the scope of AM application, as well as documenting their
12 occurrence and resolution. IPR meetings between the USACE AM teams, District
13 Commanders, and the NWD Director of Programs will be held periodically during the
14 development of the WP and in preparation for the primary science meetings. Similar
15 meetings occur among the USFWS teams, PMs, and the Region 6 Assistant Director.
16 Issues that cannot be resolved in these meetings will be elevated to the appropriate
17 district/division commands for the USACE or the Regional Director(s) for the USFWS.
- 18 For disputes between lead agencies, Inter-agency IPR meetings aimed at resolving any
19 key differences will be employed. These IPRs will generally involve the key personnel
20 from each agency involved in the dispute, along with the NWD Director of Programs and
21 the Region 6 Assistant Director. The primary objective of these IPR meetings is to
22 discuss and resolve policy issues to ensure that the Program progresses in an orderly
23 manner and that preparation and execution of the WP is not delayed. Issues that cannot
24 be resolved in these meetings will be elevated to the appropriate district/division
25 commands for the USACE or the Regional Director(s) for the USFWS. The agencies will
26 identify any significant differences and report their resolution as appropriate at MRRIC
27 meetings.
- 28 While one of the goals of the governance process for the MRRP is to facilitate early
29 coordination and cooperation among the lead agencies and MRRIC through the Team
30 structure, it is anticipated that at times the Teams may be unable to come to agreement.
31 Should this occur, it is recommended that the issue be promptly addressed through the
32 process identified below, depending on the nature of the dispute.
- 33 If the Bird or Fish Team fails to reach a consensus on the priorities for work activities,
34 they should note those differences in their report on prioritizations and
35 recommendations to the Management Team. The Management Team will consider the
36 alternate opinions when formulating the draft WP and work to resolve the issue. If the

- 1 Management Team cannot reach consensus on an issue in a timely manner or if a
2 significant difference arises from a Bird or Fish Team (e.g., regarding rejection of a
3 hypothesis and associated impacts to proposed actions), a review should be conducted
4 by the Issue Resolution Board. The Issue Resolution Board consists of the NWD
5 Director of Programs and the Special Assistant for Missouri River Programs as well as
6 Region 6 Assistant Director and the Missouri River Coordinator for the USFWS. If the
7 Issue Resolution Board cannot resolve the issue and it cannot be resolved through the
8 normal engagement process, it will be elevated to the NWD Commander for a decision.
- 9 Every effort should be made to resolve issues between MRRIC and the agencies through
10 the normal cycle of MRRIC meetings. In the event that significant differences cannot be
11 resolved through these interactions, or when disputes between the lead agencies cannot
12 be resolved by the Issue Resolution Board, the dispute will be considered by the senior
13 leadership, including the NWD Commander (or delegate), the USFWS Region 6 Director
14 (or delegate), and the MRRIC Chair. The Board or senior leadership may task the Panel
15 with reviewing matters involving interpretations of science or other technical disputes.
16 In those instances, the Panel will provide a review and written response (usually within
17 30 days) for the Issue Resolution Group's consideration.
- 18 An Issue Resolution Board review can be initiated either by request of the applicable
19 interagency Team, or by an individual agency or MRRIC after notification of the other
20 team entities. The request should include: (1) A concise summary of issues in dispute
21 and decisions that need to be made; (2) agency position statements on each of the
22 issues; (3) all supporting rationale and documentation for consideration; and (4) a brief
23 chronology of key actions taken to resolve the dispute. Resolution should be pursued as
24 quickly as possible. The MRRP Issue Resolution Board decisions should be the final and
25 binding resolution of disputes.
- 26 Each stage of the issue resolution process should take no more than 15 days. Each
27 agency and MRRIC should be prepared to make this process a priority so as to meet
28 these time frames. If resolution cannot be achieved in a lower-level interactions within
29 these time frames, the MRRIC or agencies may jointly or individually elevate the dispute
30 to the next level. In the event that such an elevation is undertaken without the full
31 consensus of the lower-level group, all other lower-level group members should be
32 notified prior to or simultaneously with the elevation.
- 33 Final decisions will be made by the USACE NWD Commander, if required, in the
34 event the Issue Resolution Board cannot resolve a dispute. If a significant dispute
35 persists at that level, the matter may be further elevated to the Chief of Engineers.
36 If not resolved at any of these levels, the Assistant Secretary of the Army for Civil
37 Works, or a designee, will make a final decision on the matter.

1 **2.5.2 Procedures for changing the governance of the MRRP AM Program**

2 Although every effort was made to identify and establish an effective governance
3 structure and process for the MRRP, periodic updates or changes to the Program's
4 governance are likely as lessons are learned regarding governance needs, to improve the
5 efficiency of the governance, or to adapt to changing Program requirements over time.
6 This section outlines the procedure for recommending, evaluating, and adopting
7 changes to the Program's governance.

8 Proposals for governance changes must originate from a Program Team (i.e., the Bird,
9 Fish, or HC Team or Management Team), a lead agency, MRRIC, Panel, or an
10 independent entity engaged to provide an external review of the Program (see Section
11 2.5.6.4). A proposal should be presented in the form of a white paper that identifies, at a
12 minimum, (a) the current governance situation, (b) the section(s) of the AM Plan
13 addressing the structure/process under consideration, (c) the suggested revision(s), (d)
14 a rationale for the change (i.e., a brief summary of the problem, benefit of the proposed
15 change, etc.), and (e) a proposed timetable for its implementation.

16 Proposals for changes to governance by any entity can be submitted to the Management
17 Team for consideration as part of the WP update process as described in Section 2.4.4.
18 Included are suggestions for adjustments to governance arising from external reviews of
19 the Program. The Management Team may add their recommendation to any proposal,
20 including suggested adjustments, but must forward the original proposal for
21 consideration and discussion at the next MRRIC meeting, or the following meeting if the
22 next meeting occurs within 15 days of a proposal receipt. MRRIC and the agencies are
23 encouraged to discuss and comment on any proposal as well as changes proposed by the
24 Management Team, and the proposal can be approved or disapproved at that meeting.
25 Rapid approval of this nature would generally be restricted to minor corrections that are
26 needed quickly or non-controversial adjustments to the composition of one Team.
27 Immediate disapproval would generally occur when a proposal conflicts with policies.

28 Two other outcomes could (and most commonly would) arise: (1) the proposal could be
29 remanded to a standing or ad hoc Team or Panel for review and input, or (2) the
30 proposal could be returned to the originating entity with suggestions for revision or
31 request for more information. In either of these cases, the revised proposal (with input
32 from the review Team/Panel or submitter's revisions) can be reconsidered and
33 discussed during any MRRIC meeting. MRRIC can make a consensus recommendation
34 regarding proposed governance changes as part of (or separate from) the
35 recommendations they make on the WP updates. The agencies may render a decision on
36 the proposal at any time following the MRRIC meeting in which it is discussed, but are
37 encouraged to wait for a recommendation if one is forthcoming. The agencies will

1 report their decision at the next MRRIC meeting following a decision, and will direct the
2 Management Team to update the AM Plan accordingly.

3 A process for reconsideration is available in the event that a decision on a governance
4 proposal causes a dispute. A reconsideration request may be made in writing to the
5 Issue Resolution Board (NWD Director of Programs, the NWD Representative, the
6 USFWS Region 6 Assistant Director, and the USFWS Missouri River Coordinator;
7 described in Section 2.5.1). The Issue Resolution Board has 30 days to (a) disapprove
8 and return the reconsideration request based on policy constraints or merit, (b) uphold
9 the request based on merit and task a Team or Panel to make suggested revisions or to
10 investigate and changes, or (c) post the request for consideration and discussion at the
11 next MRRIC meeting. Decisions of the Issue Resolution Board are made on a majority
12 basis with the MRRIC Chairperson providing a tie-breaking vote for issues involving
13 reconsideration of a governance proposal.

14 **2.5.3 Procedures for adjusting objectives, targets, or decision criteria.**

15 As learning progresses under the AM Plan, the need to update objectives, targets,
16 decision criteria, or other similar Program benchmarks may become necessary. These
17 are factors that fundamentally guide the Program, relate to ESA compliance issues, or
18 could impact HCs, so should be changed only after rigorous analysis and deliberation.

19 Recommendations for adjustments to objectives, targets or decision criteria can be
20 initiated by either of the lead agencies, by MRRIC, the Panel, by any of the Program
21 Teams, or by an independent external peer review of the Program. Recommendations
22 should be provided in the form of a white paper outlining (a) the specific objective,
23 target or criterion to be reconsidered, (b) the basis for the proposed change (studies,
24 reports, monitoring results, data, etc.), and (c) a summary of the rationale and benefits
25 of the change. The recommendation should be submitted to the Issue Resolution Board
26 (the NWD Director of Programs, Special Assistant for Missouri River Programs, USFWS
27 Region 6 Assistant Director, and the USFWS Missouri River Coordinator).

28 The Issue Resolution Board will meet to discuss the recommendation and, after
29 considering the policy, process, and programmatic implications, will determine if the
30 recommendation should be pursued further. In the event they determine the
31 recommendation should be denied without further analysis, they shall prepare a
32 statement of the rationale/basis for the decision and report that at the next MRRIC
33 meeting. If they determine the recommendation has merit, they will task the Technical
34 Team with preparation of any needed assessments/analyses (unless the underpinning
35 analyses have already been completed). The Panel (or other independent external

1 review group, if warranted) will review the supporting analyses and provide an
2 assessment of the work.

3 The following steps in the process will depend upon the nature of the proposed change,
4 and could become very involved and lengthy. Some adjustments (e.g., periodic update of
5 fledge ratios and ESH targets) may be of a nature that they can be made as a part of the
6 AM process with concurrence of the lead agencies and input/recommendations from
7 MRRIC. Other adjustments could require additional coordination, biological
8 assessments, or revisions to a biological opinion, and could necessitate re-initiation of
9 consultation on the action. Details of these alternative processes will be identified by the
10 agencies and communicated to the parties early in the process. Results of any decision
11 will be reported at the next MRRIC meeting and any agreed-upon adjustments
12 documented in the AM Plan.

13 **2.5.4 Procedure for addressing significant new information**

14 Information derived as a product of the research and monitoring of the MRRP will be
15 subjected to the review processes outlined throughout this AM Plan. Review is also
16 needed for the occasional “new information” that originates outside the Program but
17 was not identified and addressed by the Technical Team during its annual review
18 process and is of a nature that it could significantly influence Program direction. The
19 procedure outlined in this section is intended to ensure that the MRRP is using the best
20 available and verifiable science information in informing AM decisions and that it is not
21 subject to change driven by incomplete, unsubstantiated data, or research.

22 Any concerned party may bring to the MRRP new data or other information on the
23 ecology and behavior of the listed species, resources, and habitat attributes that effect
24 those species including environmental stressors, ecosystem processes that are known or
25 suspected to contribute to the survival and recovery of those species, and HC factors
26 that may affect the listed species or be impacted by efforts to protect the species. That
27 new information may include survey data that contribute to time series; analyses that
28 show linkages among the species, their habitats, and the river ecosystem, including its
29 human uses; interpretation of monitoring data; and model outputs presented with
30 mechanistic explanations for phenomena of conservation concern.

31 The identifying entity can initiate a review process to assess that new information by
32 submitting to either of the MRRP Science leads for the lead agencies an issue paper that
33 concisely explains the rationale for introducing new science information. This paper
34 does not need to document all available information; the objective is to illustrate the
35 importance of the issue and motivate a more-detailed analysis. The paper should
36 include a description of the information and its source, an explanation of its

1 management relevance, and pertinence in confronting the priority management
2 hypotheses that guide the MRRP AM Plan (and may include any non-priority
3 hypotheses that can be linked to the survival and recovery of the listed species or effects
4 of management actions taken under the MRRP). The Science Leads will make an initial,
5 joint determination on whether the new information may have relevance and
6 importance to MRRP decision making. A written evaluation will be provided to the
7 submitter. If the initial determination does not support a detailed evaluation of the
8 issue, the submitter will be given an opportunity to provide additional information.

9 If the initial determination identifies merit in the issue, the Science Leads will elevate it
10 for consideration by the Technical Team, which will engage in a “joint fact-finding”
11 process and an evaluation of the potential for that information to affect Program
12 decisions. An ad hoc joint, fact-finding team will be established and will include the
13 submitter and one or more members of the Technical Team, depending on the scope of
14 the new information. The ISP will issue a charter and identify the objectives of the joint,
15 fact-finding effort, which will generally include the compilation and analysis of all
16 available data, including new information and contextual information, to determine if
17 and how the AM process should accommodate the new information.

18 The fact-finding team in consultation with the Bird Team, Fish Team, and/or HC Team
19 (as appropriate), and in consultation with Panel, will consider whether the new
20 information provided is (or might be) reliable knowledge (constitutes best available
21 science) that warrants consideration in the AM program planning process. Only if so,
22 then the fact-finding team will provide a study plan to the ISP and, after review by the
23 ISP and the Panel, proceed with additional data gathering and/or directed studies to
24 substantiate the phenomenon of concern. The fact-finding team will provide the ISP
25 with monthly status reports (if the effort spans more than 2 months) and will participate
26 in a mid-point review conducted by the ISP to ensure the effort is proceeding toward
27 resolution and is utilizing accepted standards of practice. The fact-finding team will
28 produce a draft report with analysis of the new information, analysis of how the new
29 information relates to decisions and management actions, and a draft recommendation
30 for disposition of the issue. Recommended disposition may include the following.

- 31 • Note the issue but take no further action (based on lack of merit, no clear
32 relationship to management actions, etc.).
33 • Recommend additional study (including identification of additional data or scientific
34 information/analyses required to clarify the issue).
35 • Elevate the issue to a new action hypothesis to be addressed through the MRRP AM
36 process.

1 The draft report and all data will be provided to the ISP, which will schedule a review
2 and comment period and formal presentation of the study and findings. Review
3 comments may be provided by the agencies and by the Panel. The fact-finding team will
4 respond to comments and the revised document will be submitted to the Panel for final
5 review and concurrence /comment. (Note: The submitting entity has participated in the
6 evaluation as a member of the fact finding team and therefore will not be engaged for
7 further comment on the final product). If the Panel does not concur, the issue will be
8 sent back to the fact-finding team for further consideration. In the event further
9 consideration does not alter the position of either the fact-finding team or the Panel, or
10 if the submitting entity disagrees with the outcome, the issue may be elevated to the
11 Issue Resolution Board (NWD Director of Programs, the NWD Representative, the
12 USFWS Region 6 Assistant Director and the USFWS Missouri River Coordinator), and
13 Third Party Science Neutral (TSPN) for consideration. The TSPN serves as an ad hoc
14 member of the Board for issues related to new information. The Board, by majority vote,
15 determines the disposition of the issue using the above list of potential outcomes. The
16 Board reports its findings to the originator of the issue and at the next MRRIC meeting.

17 **2.5.5 Procedures for elevating and relegating hypotheses**

18 This procedure applies to the management of the broad suite of hypotheses identified in
19 the CEMs, described in the EA reports, and highlighted in various sections of the AM
20 Plan. Hypotheses can be elevated from or moved into reserve as information and
21 understanding dictates. The reserve includes those hypotheses (1) below a priority
22 threshold, (2) having no clear mechanism for investigation or testing, and/or (3) outside
23 current USACE authorities.

24 As learning occurs through the AM cycle, the list of hypotheses may expand or contract
25 beyond the initial set of hypotheses identified in the EA reports. Hypotheses that are
26 implemented and found to not be effective can be moved into the reserve, and
27 hypotheses that show merit based on research or other further analyses, new
28 information, or improved understanding can be elevated into the active hypotheses
29 category. The Technical Team will be charged with an annual hypothesis evaluation and
30 will report the findings of this evaluation at the Annual AM Workshop.

31 Based on the analyses of the Technical Team, the Bird and/or Fish Team may
32 recommend the elevation of any reserve hypothesis, and may include prioritized studies
33 or actions to address that hypothesis in the WP development process. The Management
34 Team may also recommend elevation of a reserve hypothesis, independently of the
35 Bird/Fish Team recommendations. The process for approving the elevation of reserve
36 hypotheses or relegation of current working hypotheses to the reserve is similar to the

1 process changing species objectives, targets, or decision criteria highlighted in Section
2 2.5.3. Elevation/relegation can also be recommended by MRRIC or agency leadership.

3 In the event the recommendation is made by the Bird and/or Fish Team and is
4 subsequently supported by the Management Team and approved as part of the WP
5 Process, no further action is required. In the cases where the recommendation is made
6 without concurrence at each level, a reevaluation of hypotheses will be performed by the
7 Technical Team and their findings reported and reviewed by the Panel (Note: An
8 exception is made in cases where the hypothesis is relegated to reserve status by
9 policy/authority factors; in those instances the agency makes the determination and
10 reports its rationale at the next MRRIC meeting). The Technical Team's report and the
11 Panel evaluation are submitted to MRRIC and the agencies for review/discussion.
12 Oversight's decision regarding the recommendation is recorded and communicated
13 through a decision document.

14 **2.5.6 Independent external review**

15 The MRRP maintains several established Peer Review Processes to allow for the review
16 of the Program, monitoring and study plans and reports, project designs, and the
17 science program. Assurance that these and other products used for decision making in
18 the AM Plan are of the highest quality and meet standards of practice is essential to trust
19 building and program success. The peer review process relies upon good QC and peer
20 review at the district level as well as external product/program review using
21 independent panels selected because of their expertise on the specific subject matter.
22 These panels are convened to do the reviews only and are not on-going or permanent
23 components of the program, with the exception of the Panel.

24 All Civil Works planning, engineering, and O&M products must undergo review (see EC
25 1165-2-209; USACE 2010). All products undergo District Quality Control (DQC), and a
26 subset of these undergoes ATR. Smaller subsets of the ATR group undergo IEPR. Peer
27 reviews are critical to high-quality decision and implementation documents.

28 *2.5.6.1 District Quality Control (DQC)*

29 DQC is an internal review process of basic science and engineering work products
30 focused on ensuring the quality requirements of the AM Plan are met. DQC consists of
31 quality checks and reviews — routine checks and reviews carried out during the
32 development process by peers (i.e., supervisors, team leaders, other senior personnel)
33 not responsible for the original work — conducted for any science and/or engineering
34 product under the MRRP. Documentation of all DQC activities is required. The NWK
35 and NWO districts will manage the DQC process in accordance with USACE policies.

1 2.5.6.2 *Agency Technical Review (ATR)*

2 ATR is undertaken to “ensure the quality and credibility of the government’s scientific
3 information” and was previously referred to as “Independent Technical Review” (ITR).
4 It is mandatory for all decision and implementation documents and other work
5 products, according to a case-specific, risk-informed decision (see EC 1165-2-209 and
6 08502-CENWD-RBT on EC 1165-2-209.). Decision documents are planning
7 feasibility/reevaluation studies or other project studies that require NWD/HQUSACE
8 approvals. Implementation documents are generated subsequent to decision
9 documents and lead to the implementation of the selected action. Reviews are
10 conducted by professionals outside of the MRRP districts and not affiliated with the
11 development of the project or product. The required ATR team member disciplines and
12 expertise are described in the Master Review Plan. At the conclusion of the ATR, the
13 team prepares a review report, which is then certified by the NWD.

14 2.5.6.3 *Independent External Peer Review (IEPR) of MRRP Projects*

15 IEPR is the most independent level of review, applied in cases where the risk and
16 magnitude of the proposed project are such that a critical examination by a team outside
17 of the USACE is warranted. IEPR panels are made up of independent, recognized
18 experts in the appropriate disciplines and are selected using the National Academies of
19 Science (NAS) policy for selecting reviewers.

20 There are two types of IEPRs. Type I IEPR is conducted on decision documents and
21 supporting work products where there are public safety concerns, significant
22 controversy, a high level of complexity or significant economic, environmental, and
23 social effects to the nation. Type II IEPR is conducted on design and construction
24 activities for hurricane and storm risk management and flood risk management
25 projects, as well as other projects where potential hazards pose a significant threat to
26 human life. This applies to new projects as well as major repairs, rehabilitations,
27 replacements or modifications of existing facilities. A third category, Special Case IEPR,
28 is required when a non-Federal interest undertakes a study, design, or implementation
29 of a Federal project, or requests permission to alter a Federal project. The non-Federal
30 interest must make a risk-informed decision on whether to undertake a Type I and/or
31 Type II IEPR, and this decision process and the reviews must be included in the
32 documents submitted for review or approval.

33 2.5.6.4 *Independent External Peer Review of the MRRP*

34 An IEPR of the MRRP should be held after its third and sixth year of operation. Further
35 IEPR needs should be reassessed following the second review. The review should be
36 conducted by an independent entity with related expertise and experience. The scope of

1 the review should be broad, with the aim of (1) identifying overall program performance
2 towards its goals and (2) identifying mechanisms/changes to improve its capacity toward
3 achieving those goals. Included are assessments for the subprograms (birds and fish), as
4 well as for the overall program and its governance. The review should assess the
5 performance of the agencies and of MRRIC, and should make recommendations for the
6 improvement of the Program, its components, and its participants. Reviewers should
7 prepare a report, and an executive summary, to be submitted to the agencies and
8 MRRIC for consideration. Details on the Programmatic IEPR are presented in
9 Attachment 13 of Appendix A.

10 **2.5.6.5 ISP review process**

11 The ISP has a science QA process that includes both internal and external reviews to
12 ensure integrity and independence are maintained in the ISP and its products. Internal
13 review involves technical review by PDTs and technical leads, and managerial review of
14 products by the ISP PMs and ISP Management Team (MT). External review is
15 conducted on an as-needed basis and involves ISR and peer review by individuals
16 outside of the action and partner agencies.

17 The MRRP's Panel is an example of an ISR panel that provides advice on specific topics.
18 This group is a neutral group with expertise retained by the MRRP to provide
19 independent and objective guidance to the program. A Panel review could occur at any
20 level, program, project, study, or report. The Panel can comprise up to six science
21 advisors who meet at least annually and are charged with independent science support
22 and technical oversight. Topics originate from the USACE and/or MRRIC. The general
23 disciplines of expertise on the panel include: Aquatic/Riverine Ecologist, River
24 Hydrologist/Geomorphologist, Least Tern/Piping Plover Specialist, Sturgeon Specialist,
25 Quantitative Ecologist/Statistician, and Conservation Biologist. The Panel website is
26 <http://projects.ecr.gov/moriversciencepanel/default.aspx>.

27 **2.5.7 Requirements for research and focused study efforts**

Note: This section will be further developed by the AM Team in
consultation with the ISP. Appendix J will address details.

28

29 The PI for any funded research effort or the Lead Investigator for any Monitoring
30 Program or focused study effort will be required to develop and maintain a Project
31 Management Plan (PMP) for the effort. A project management plan (PMP) is a formal,
32 living document used to define requirements and expected outcomes and guide project
33 execution and control. All continuing MRRP projects are required to develop and

- 1 maintain a PMP (5–10 pages). Yearly updates of the PMP will be due at the Fall Science
2 Meeting for the program (generally occurring in September). However, the ISP
3 Manager should be informed of significant deviations from the PMP at the earliest
4 possible opportunity during the course of the FY. See Attachment 1 of Appendix J for a
5 PMP template.
- 6 Each PI or Lead Investigator will also be asked to prepare and maintain a Fact Sheet
7 (see Attachment 8 of Appendix A for a template) and provide quarterly progress reports
8 on products and expenditures.
- 9 Investigators undertaking research funded by the MRRP are obligated to participate in
10 two In-Progress Reviews (IPRs) annually. In addition to oral presentations at each IPR,
11 the PI will submit the required documentation of research progress and milestone status
12 shown in Attachment 3 of Appendix J. PIs can elect to have a colleague present at an
13 IPR, but is responsible for ensuring the alternate is sufficiently familiar with the work to
14 answer detailed technical questions regarding the work. Inability to substantially defend
15 a research effort is grounds for termination of funding for the effort.
- 16 Technical publications from the MRRP will adhere to the guidelines in Attachment 2 of
17 Appendix J unless required by their agency to use a different set of guidelines and after
18 obtaining approval of the ISP Manager. All data collected and/or used to support
19 analyses shall be furnished to the ISP following the guidelines and procedures outlined
20 in Chapter 6.

21 **2.5.8 Agendas for the Fall Science Meeting and for the Annual AM Workshop**

22 Attachment 8 of Appendix A presents the standing agendas for the indicated
23 meetings/workshops. These agendas can be modified at the discretion of the ISP
24 Manager to include issues, but the meeting/workshop should address all of the topics on
25 the standing agenda.

26 **2.5.9 Guidelines for technical publications**

27 Research reports and findings of monitoring and assessments constitute important
28 products of work under the MRRP. They influence important decisions regarding
29 program implementation. Money, facilities, and talent devoted to research should
30 always result in a formal technical communication of some kind. It is important that
31 reports be published in a timely fashion, be clearly and concisely written, and be
32 technically correct. The content of a report and the manner of presenting data are
33 governed by the objectives of the investigation and the distribution intended. The ISP
34 Manager may prescribe the level of detail of a report prepared for specific needs.

1 Attachment 9 of Appendix A provides guidelines for technical publications of the
2 Program.

3 **2.5.10 Example Fact Sheet**

4 Fact sheets outlining the purpose, approach, products, significant findings, and a point-
5 of-contact for research efforts, studies, significant analyses, or other activities of the
6 MRRP are recommended as a mechanism for informing MRRIC and stakeholders of
7 program activities. Attachment 8 of Appendix A provides a template and guidelines for
8 developing and posting fact sheets.

9 **2.5.11 Cultural Resource Plan**

10 Attachment 12 of Appendix A includes a Cultural Resources Plan for the MRRP. The
11 plan addresses the combined requirements of the following:

- 12 • Executive Order 13175, Consultation and Coordination with Indian Tribal
13 Governments, 06 November 2000
- 14 • White House Memorandum, Government-to-Government Relations, 29 April 1994
- 15 • U.S. Army Corps of Engineers (USACE) Tribal Policy and Principles, 18 February,
16 1998 and 10 May 2010
- 17 • DOD American Indian and Alaska Native Policy, 20 October 1998
- 18 • Presidential Memorandum, Tribal Consultation, 05 November 2009
- 19 • Department of Army American Indian and Alaskan Native Policy, 24 October 2012
- 20 • USACE Memorandum for Commanders, Directors and Chiefs of Separate Offices,
21 U.S. Army Corps of Engineers, Subject, Tribal Consultation Policy, 01 November
22 2012
- 23 • Planning, Environmental Resources, Fish Policy and Support Division: Native
24 American Policy CENWD-PDD Policy Memorandum, No. NWDOM 200-1-1
- 25 • Missouri River Master Manuel Environmental Impact Statement Appendix A Section
26 14 Government-to-Government, March 2004.

27 **2.5.12 Program priorities development process**

28 There are two types of priority setting within the MRRP. The first type is the annual
29 request for appropriations, and this is implemented as part of the Corps' 3-year budget
30 cycle process. For example, prioritization during FY18 will provide planning
31 information for implementation of projects in FY20. NWO has the responsibility for
32 requesting the appropriations for the overall program including resources for both
33 districts (NWO and NWK). Appropriation requests are based on three priorities:

- 1 1. *Minimum Compliance*: Projects that ensure that The USACE would be in
2 compliance with the BiOp for the appropriation year. This includes continuing
3 contracts and projects that were awarded in a previous year and the real estate
4 acquisitions to ensure compliance with habitat requirements in out years (i.e., it
5 takes a minimum of two years from acquisition to habitat development on most
6 acquired properties).
- 7 2. *Long-term Compliance*: Projects that ensure compliance with the BiOp and the
8 Mitigation Program in the out years, particularly for any BiOp “check-in” years.
- 9 3. *Capability*: Projects that ensure program capability (i.e., the amount of work that
10 can be accomplished in both districts in that FY). Appropriation requests rarely align
11 with actual appropriations.

12 BiOp activities are initially prioritized within the multi-agency Bird, Fish, and HC Teams
13 based on decision criteria for their priorities and then elevated to the Management
14 Team for integration into the overall budget, which is ultimately approved by the NWD
15 Director of Programs.

16 The second type of priority setting is the development of the WP for implementing the
17 actual appropriation (see Section 2.4.4). At the program-level, priorities for the MRRP
18 are linked to the mission, vision, and scope of the program as well as the BiOp and
19 enabling legislative acts (e.g., WRDA 2007). MRRP priorities may change significantly
20 from one FY to the next because (a) system conditions change, creating both demands
21 (e.g., need to build ESH) and opportunities (e.g., storage for a flow release), and (b)
22 information from research and ecosystem monitoring and assessment may reveal the
23 need for significant shifts in program focus.

24 **2.5.13 Cost management**

25 The MRRP cost management program includes planning, estimating, budgeting, and
26 controlling costs so that program execution and recovery projects can be completed
27 within approved budgets. There are three critical elements associated with MRRP cost
28 management: (1) cost estimating – developing an approximation of the costs of
29 resources needed to complete program management activities of restoration projects;
30 (2) cost budgeting – aggregating the estimated costs of individual activities to establish
31 an annual MRRP cost budget for each FY; and (3) cost control – monitoring the factors
32 that create cost variances and controlling approved changes to the MRRP budget. An
33 MRRP cost management plan is being prepared and will become an essential
34 component of program execution.

1 2.5.13.1 *Cost management plan*

2 The MRRP will develop a broad, formal cost management plan; the MRRP PM has the
3 responsibility for development and implementation of this plan. The cost management
4 plan will clearly define how MRRP funding will be managed throughout the program's
5 lifecycle. The plan will identify the processes and procedures by which MRRP program
6 and project costs are estimated, measured, and controlled. Additionally the plan will
7 outline the following.

- 8 • Who is responsible for management of program and project costs.
9 • Who has the authority to approve changes to program and project budgets.
10 • How MRRP costs are quantitatively measured and reported.
11 • What is the proper format and frequency of financial reports, and to whom they are
12 presented.

13 2.5.13.2 *Cost estimating*

14 An initial estimate of MRRP project costs is developed for each PMP based on the
15 project's Work Breakdown Structure (WBS). Estimates are based on experience with
16 similar projects taking into account site-specific conditions. Cost estimates are further
17 refined and detailed during development of the Project Implementation Reports (PIRs),
18 land acquisition appraisals, or scopes of work for ISP activities. Cost estimates are
19 prepared to the level of the WBS needed by PMs to effectively monitor project budgets
20 and track project execution, as determined by the project schedule.

21 2.5.13.3 *Annual cost budgeting*

22 Annual project budgeting involves allocating the overall cost estimate to individual
23 activities identified in the project WBS. An annual MRRP budget is developed by using
24 the project cost estimate, anticipated research funding needs, and baseline subprogram
25 costs to estimate costs for each subprogram. The SPM coordinates with the PMs to
26 ensure budgets for each MRRP subprogram and project are reasonable, and to assess
27 risks/impacts and develop contingencies for alternative budget amounts. These
28 individual subprogram budgets are integrated and added to other programmatic costs
29 (cost for Program integration and administration, MRRIC, etc.,) and used to develop an
30 annual program-scale cost budget for the MRRP.

31 Annual MRRP budget exercises already utilize cost estimating techniques by using three
32 budget scenarios – compliance, long-term compliance, and capability. These budget
33 scenarios allow the Management Team, ESC, and District leadership to estimate costs
34 each FY given the fluctuations in annual appropriations; they also provide transparency
35 to the budget process by clearly indicating what is funded under each scenario.

1 2.5.13.4 *Cost control*

2 MRRP programmatic activity costs are the responsibility of the SPM while the other
3 PMs are responsible for individual restoration project budgets. PMs review biweekly
4 Financial Management Reports to ensure the correct labor charges have been made and
5 all contractor costs are correct. PMs communicate with members of the PDT regarding
6 progress on individual activities throughout the program/project lifecycle and bring any
7 problems to the attention of the SPM. The SPM, in turn, alerts the ESC of any budget
8 problems that cannot be resolved by the SPM. A list of factors that generally cause cost
9 variances is used to inform the SPM and PMs so that they are aware of potential budget
10 risks. Quantitative cost thresholds are also defined up front and used to identify when
11 corrective action is required (e.g., program/project is over budget). Finally, a list of
12 corrective actions is prepared in advance and used in the event that changes to the
13 budget are needed.

14 2.5.13.5 *Cost change control approval process*

15 When an established cost threshold for a specific MRRP project/activity is triggered, the
16 change control process is initiated. The SPM evaluates the request and makes a
17 determination for changes under <\$50,000>; the ESC considers and approves changes
18 over this amount. Project budgets are adjusted and documented to reflect approved
19 revisions.

20 2.5.13.6 *Value Management (VM) and Value Engineering (VE)*

21 A VM/VE study should be conducted for all individual habitat development projects that
22 exceed \$2 million (ER 1110-1-12; USACE 2006). The PM and PDT will work with the
23 District Value Engineering Officer to decide if a cost-effectiveness review or VM/VE
24 study is required. Because a preliminary cost estimate will be completed during the PIR
25 phase for each site, this is when the decision is made regarding VM/VE study need.

26 The goal of a VM/VE study is to assure that the most cost-effective approach is taken
27 while meeting the project objectives. Study teams should include USACE and
28 Mitigation ACT personnel experienced with the program and seek, to the extent
29 possible, to maximize development and sharing of lessons learned between the two
30 districts. PMs will review all construction contracts to ensure that Contract Clause
31 52.248-3 “Value Engineering-construction” is included. This contract clause encourages
32 the construction contractor to develop, prepare, and submit VM/VE proposals (i.e.,
33 VECPs) during the course of habitat development activities. If an event or process is
34 identified during any VM/VE study that is significant enough to warrant a change in any
35 processes outlined in this AM Plan, it should be brought to the attention of the SPM for
36 change management procedures.

1 PMs will undertake steps to ensure the most cost effective techniques are employed,
2 allowing for the need to implement experimental designs that sometimes call for actions
3 with varying costs so they may be properly evaluated. Management actions should be
4 designed to take advantage of natural river processes as much as practical, following the
5 "Engineering With Nature" principles endorsed by the USACE. For actions at Levels 3
6 and 4, the PDT will seek, where possible, design standards and criteria based on the
7 lessons learned from those previous projects so as to most cost-effectively meet
8 objectives given site/system/program constraints.

9 **2.5.14 Program safety and health requirements**

10 The Safety and Occupational Health Managers (SOHM) are responsible for the District
11 Safety and Occupational Health Program (SOHP). The SOHM is responsible for
12 planning, organizing, overseeing, and evaluating the SOHP, in conjunction with the
13 PgM. The SOHM reviews the Site Safety and Health Plan (SSHP), if required. The
14 SOHM or staff conducts periodic safety surveys, inspections, evaluations of all work and
15 procedures associated with the project to include operational procedures, programmatic
16 safety and occupational health requirements, environmental hazards that could be
17 encountered, construction, recreational and public protection from safety hazards, and
18 personal protective equipment requirements. The SOHM ensures compliance with all
19 applicable safety regulations and provides support to the PgM/PM for overall safety on
20 the project site. Safety requirements for the MRRP are presented in Attachment 13 of
21 Appendix A.

3.1 Adaptive Management for Plovers and Terns

2 This chapter is organized according to the five steps of the AM cycle introduced in
3 Section 1:

- 4 1. Assess (Section 3.1), which provides objectives and scope for piping plover and
5 least tern management and summarizes the EA.
- 6 2. Plan and Design (Section 3.2), which outlines the bird AM framework,
7 performance metrics, and management conditions, targets, and specifies
8 management actions and associated decision criteria.
- 9 3. Monitor (Section 3.3), which summarizes the metrics used for monitoring habitat
10 and species status, action effectiveness, and monitoring to capture outcomes of
11 unusual events.
- 12 4. Implement (Section 3.4), which summarizes steps in carrying out management
13 actions.
- 14 5. Evaluate (Section 3.5), which summarizes the evaluation of habitat and
15 population status, management conditions and options, key relationships and
16 new information, model updates and validation, and the use of ancillary
17 information and unexpected events.
- 18 6. Decide (Section 3.6), which summarizes key management decisions and
19 associated tools including predictive models, and decisions to reevaluate metrics
20 and targets.

21 Associated appendices include Appendix A (Protocols and procedures for decisions),
22 Appendix B (CEMs), and Appendix G (Monitoring protocols related to the birds).

3.1.1 Assess

3.1.1.1 Management objectives and scope for least terns and piping plovers

25 The fundamental objectives for piping plovers and least terns, initially drafted by the
26 USFWS in 2013, are as follows:

27 *Fundamental Objective. Avoid jeopardizing the continued existence of
28 the piping plover due to the U.S. Army Corps of Engineers actions on the
29 Missouri River.*

30 *Fundamental Objective. Avoid jeopardizing the continued existence of
31 the least tern due to the U.S. Army Corps of Engineers actions on the
32 Missouri River.*

1 Sub-objectives for piping plovers were also drafted by the USFWS in 2013 and have
2 been revised for clarity and specificity during the AM Plan development process.

3

4 *Sub-objective 1 (Distribution). Maintain a geographic distribution of plovers in*
5 *the river and reservoirs in which they currently occur in both the Northern*
6 *Region (Missouri River from Fort Peck Lake, Montana to Fort Randall Dam,*
7 *South Dakota, including reservoir shorelines) and Southern Region (Missouri*
8 *River from Fort Randall Dam, South Dakota to Ponca, Nebraska)*¹.

9

10 *Sub-objective 2 (Population). Maintain a total population number of Missouri*
11 *River piping plovers that has a 95% probability that at least 50 individuals will*
12 *persist for at least 50 years within both the Northern and Southern Regions.*

13

14 *Sub-objective 3 (Population Trend). Maintain a stable or increasing long-term*
15 *trend in population size within both regions.*

16

17 *Sub-objective 4 (Reproduction). Maintain fledgling production of breeding pairs*
18 *at least sufficient to meet the population growth rate objectives within both*
19 *regions.*

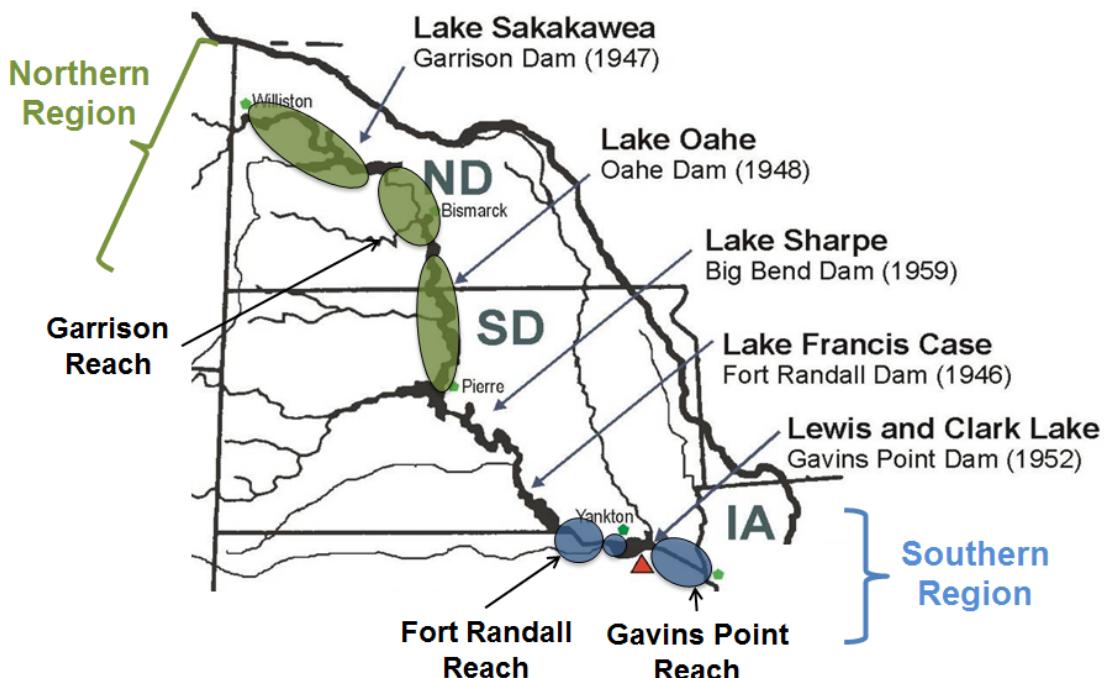

20 3.1.1.1 Geographic scope

21 The geographic scope of the AM Plan for piping plovers and least terns is the mainstem
22 Missouri River from the upper end of Lake Sakakawea near Williston, ND, to Ponca, NE.
23 Plovers and terns nest in six segments within this geographic area (Figure 36):

- 24 1) Lake Sakakawea (shoreline of the impounded river above Garrison Dam; RM 1568-
25 1389.9)
26 2) Garrison Reach (riverine segment between Garrison Dam and Lake Oahe; RM
27 1389.9-1304)
28 3) Lake Oahe (shoreline of the impounded river above Oahe Dam; RM 1304-1072.3)
29 4) Fort Randall Reach (riverine segment between Fort Randall Dam and Lewis and
30 Clark Lake; RM 880-845)
31 5) Lewis and Clark Lake (delta segment between Fort Randall Reach and the
32 impoundment of Lewis and Clark Lake; RM 845-811.1)
33 6) Gavins Point Reach (riverine segment below Gavins Point Dam and above the
34 channelized river beginning at Ponca, NE; RM 811.1-754).

¹ These regions correspond with two regions (Northern Rivers and Southern Rivers) of the four identified in the *Draft Revised Recovery Plan for the Northern Great Plains Piping Plover* (USFWS 2016). The Southern Region as referred to in this document, however, references only the Missouri River mainstem components and not the tributaries included in the recovery plan.

1

2

3 Figure 36. Geographic scope of AM Plan for terns and plovers.

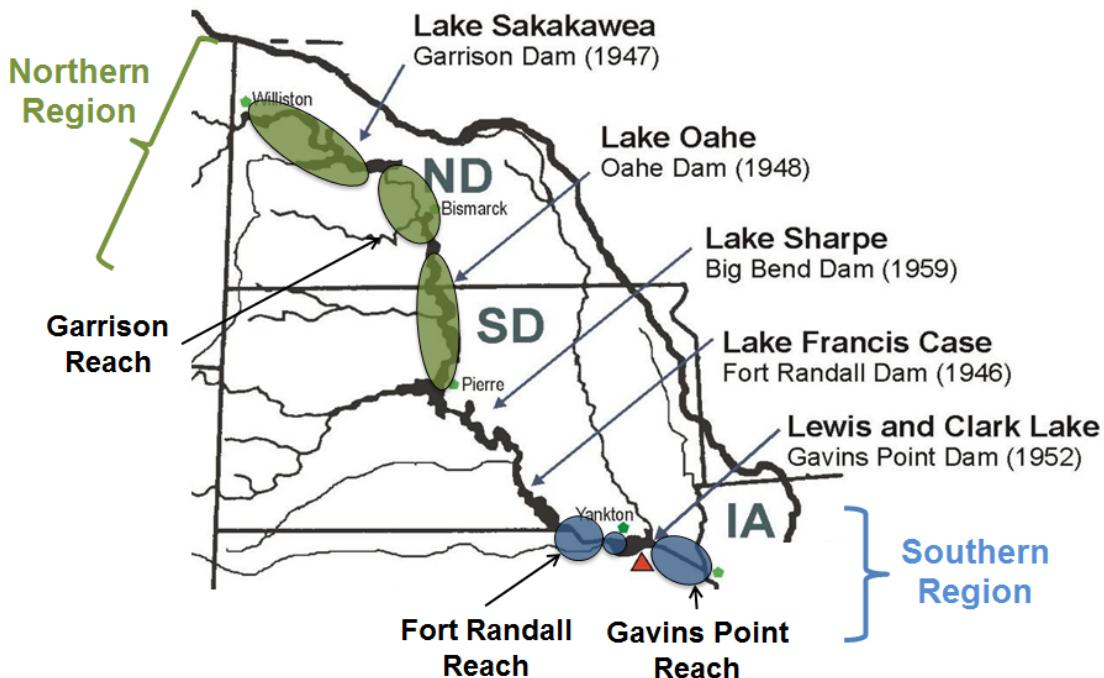

4 Limited nesting also occurs in the Fort Peck reach upstream of Lake Sakakawea, but as
 5 very few plovers have been observed to use habitat on that reach or on Ft. Peck Lake¹, it
 6 is not included in the focal areas for plover management.

7

8 The design and operation of Lake Sharpe and Lake Francis Case provides little to no
 9 nesting habitat. This gap in habitat availability between Lake Oahe and Fort Randall
 10 Reach creates a dispersal barrier. Piping plovers have been observed to have high site
 11 fidelity, (i.e., they are likely to return to their previous breeding area). Plovers that
 12 disperse are more likely to move within segments or between segments within a region
 13 than to return to breed in the other region. Therefore, for planning, modeling, and
 14 target-setting purposes, the mainstem breeding areas have been divided into two

¹ Since 1997, 0%–2% of the observed plover population used habitat along Fort Peck Lake or in the reach upstream of Lake Sakakawea. The average was <1% of the plover population.

1 regions, as indicated in

2
3 Figure 36. The Northern Region includes Lake Sakakawea, Garrison Reach,
4 and Lake Oahe. The Southern Region includes Fort Randall Reach, Lewis and Clark Lake,
5 and Gavins Point Reach.

6
7 The geographic scope reflects the decision-making authority of the USACE. The effects
8 of nearby subpopulations of piping plovers and least terns on MRMS populations
9 (metapopulation dynamics) are not fully understood, and considered a critical
10 uncertainty within the AM Plan (Section 3.1.2.5). Studies underway to measure
11 dispersal between the MRMS and other breeding areas will provide information on
12 metapopulation dynamics. As results become available, the ability to account for and
13 model metapopulation dynamics will be evaluated and developed to the extent possible.

14 3.1.1.2 Relationship to species recovery

15 The *Draft Revised Recovery Plan for the Northern Great Plains Piping Plover*
16 (*Charadrius melanotos*), First Revision (henceforth, Plover Recovery Plan; USFWS,
17 [2016]) identifies four recovery regions (sub-populations) of Northern Great Plains
18 plovers: Prairie Canada, U.S. Alkaline Lakes, Northern Rivers, and Southern Rivers. The
19 mainstem Missouri River comprises the entirety of the Northern Rivers region and a
20 substantial portion of the Southern Rivers region, which also includes the Niobrara,
21 Loup, and Platte Rivers. The Plover Recovery Plan emphasizes the importance of
22 maintaining sufficient habitat in each of the four regions, given the contribution of each
23 region to the overall geographic area and habitat diversity and the limited dispersal
24 observed between regions:

1 The population should be broadly distributed to reduce the risk of loss of a
2 significant proportion of the population. It is important for the population to
3 be distributed through the range to maximize viability into the future and to
4 reduce the risk of a stochastic event impacting a large proportion of the
5 population. (USFWS 2016)

6 The plan also identifies the importance of maintaining a diversity of habitat types,
7 including riverine sandbars, and of not relying on human-created, off-river habitats as a
8 means of achieving long-term recovery. In the MRRP planning area, which includes the
9 river and the meander belt, the plover nearly exclusively nests on in-channel islands and
10 along reservoirs. A very high proportion of recorded plover nesting on riverine islands
11 occurs on the Missouri River. Accordingly, to meet the range-wide goal of conserving
12 piping plovers across as much of their historical distribution as possible and in the full
13 breadth of its known habitats, the MRRP should focus on providing in-channel habitat
14 in an extent and condition sufficient to support stable demographic units that can
15 persist in the face of dynamic environmental conditions

16 The objectives for the MRRP, as identified above, are to avoid jeopardy to the listed
17 species, not meet requirements for recovery. To the extent that the MRRP can support
18 recovery of the piping plover, it will provide clear benefits to the species and program;
19 however, the MRRP currently has defined targets (Section 3.2.3) that differ from
20 recovery targets, because both the objectives and the methodology for defining targets
21 differ (USFWS 2016). The USFWS has determined that these differences are acceptable
22 and appropriate and do not create a conflict between the Plover Recovery Plan and the
23 MRRP. If, in the course of AM within the MRRP or following updates to the Plover
24 Recovery Plan, the need to adjust MRRP plovers target criteria is identified, that process
25 is defined in Sections 3.6.1 and 3.6.5.

26 The fourth recovery criterion identified in the Plover Recovery Plan is the following:

27 Criterion 4: Ensure commitments are in place and functioning as
28 anticipated to provide long-term funding, protection, and conservation
29 management activities in essential breeding and wintering grounds. ...

30 *Purpose: To make sure that management commitments necessary for*
31 *piping plovers' continued persistence are in place and functioning, and will*
32 *continue to operate after the species is recovered.*

33 In the event the first three recovery criteria are met throughout the range of the
34 Northern Great Plains Piping Plover, the MRRP (and other resource management
35 agencies in the range) will need to demonstrate the commitment to continue providing
36 habitat, population protection, and related management actions. Some requirements
37 may change from the current MRRP objectives, but species recovery will not result in
38 cessation of management for plover and tern habitat on the MRRP.

1 The Plover Recovery Plan identified reservoirs, channelization of rivers, and
2 modification of river flows; invasive species and vegetation growth; and inadequacy of
3 existing regulatory mechanisms as high threats for both the Northern Rivers and
4 Southern Rivers regions. Density leading to intraspecific aggression, agricultural
5 development, predation, and human disturbance were identified as high or medium
6 threats to both regions. These stressors overlap strongly with the threats identified in
7 the piping plover EA as explained in Section 3.1.2.

8 The 5-year review of the Interior Least Tern recommended delisting (USFWS 2013).
9 Delisting requires a conservation plan and post-delisting monitoring plan from
10 cooperating agencies, similar to what is described above for plovers. The MRRMP will
11 also serve as the conservation plan for interior least terns and must therefore
12 demonstrate the ability to continue meeting habitat and population protection needs for
13 least terns.

14 **3.1.2 Key findings from Effects Analysis (EA)**

15 **3.1.2.1 Purpose and methods of the EA**

16 An EA was undertaken to address the requirement within the ESA to use the best
17 available science to evaluate the effects of actions proposed by federal agencies on listed
18 species or designated critical habitat. The EA adapted the rigorous approach advocated
19 by Murphy and Weiland (2011). Before the EA began, the problem was formulated with
20 the definition of the proposed action, the area affected, and a conceptual model of the
21 physical and biological relationships relating actions to species outcomes. After problem
22 formulation, the first step in the EA was to collect reliable scientific information,
23 including observations about the stressor(s), the range of stressor conditions and
24 information on population sizes and trends. The second step included assessment of the
25 data, the use of quantitative models to synthesize existing information, and
26 identification and representation of uncertainties. The third step was to analyze the
27 effect of the actions on the species to determine costs and benefits and identify
28 alternative management approaches.

29 This section summarizes the EA for plovers and terns as documented in the following
30 reports:

- 31 • Summaries of the state of science for the species and their habitats to identify the
32 effects of system operations and actions on species populations and their habitats
33 (Buenau et al., 2015z)
34 • Conceptual Ecological Models (CEMs) and hypotheses addressing critical
35 uncertainties (Buenau et al. in prep)

- 1 • Quantitative assessments and modeling evaluating the effects of management
2 actions on habitat and population dynamics (Buenau et al. in prep.)
- 3 The EA used the information and tools described in these reports to provide an
4 integrated assessment of the effects of management actions on piping plovers and least
5 tern habitat and populations in the Missouri River. It also documents and synthesizes
6 the uncertainties in the assessments. The foundation of the EA is the habitat and
7 population models, which synthesize available information to make predictions, assess
8 management hypotheses, predict outcomes of combinations of management actions
9 under evaluation for the Management Plan, calculate numerical targets, and quantify
10 uncertainties and their impacts on management decisions. These tools will continue to
11 be applied and refined through the AM process.

12 *3.1.2.2 Conceptual ecological model*

13 The CEMs for plovers, terns, and their habitat relate drivers (social, political, legal, and
14 economic; climate, geology, and land use) to Missouri River management, hydrology,
15 and habitat. They then relate habitat availability to biotic processes: nesting behavior,
16 predation and food availability, and dispersal. These biotic factors affect survival and
17 reproduction to ultimately determine population size. An overview conceptual model is
18 shown in Figure 37. Complete conceptual models for each species are shown in
19 Appendix B. In the complete models, the estimated importance of each relationship is
20 indicated by the type of arrow, with thick solid lines representing the most important
21 relationships and thin dot-dash lines representing the least important relationships.
22 Importance was determined based on the relative effect of each relationship to the
23 affected factor. Uncertainty is reflected by arrow color. Uncertainty in the CEMs
24 represents lack of knowledge, high natural variability, or both.

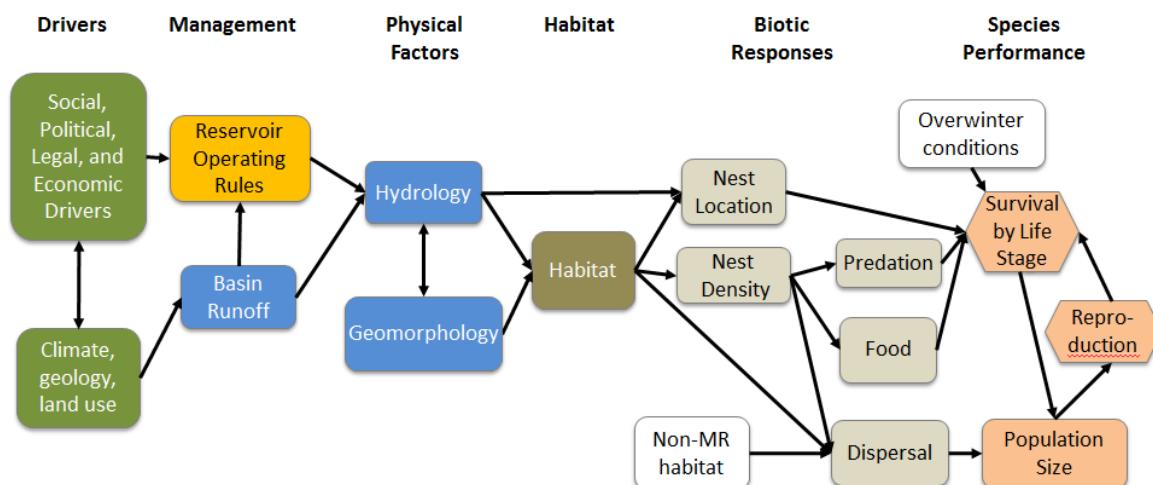

25 The CEMs were initially developed in a set of inter-agency workshops in 2013, then
26 reviewed, revised, and used to develop biological and management hypotheses to be
27 evaluated in the EA.

28 *3.1.2.3 Quantitative modeling framework*

29 The quantitative modeling framework includes components for hydrology, riverine and
30 reservoir shoreline habitat, and population viability (Figure 38). These components are
31 briefly described here. Details can be found in Fischenich et al. 2015 and Buenau et al.
32 (in prep.).

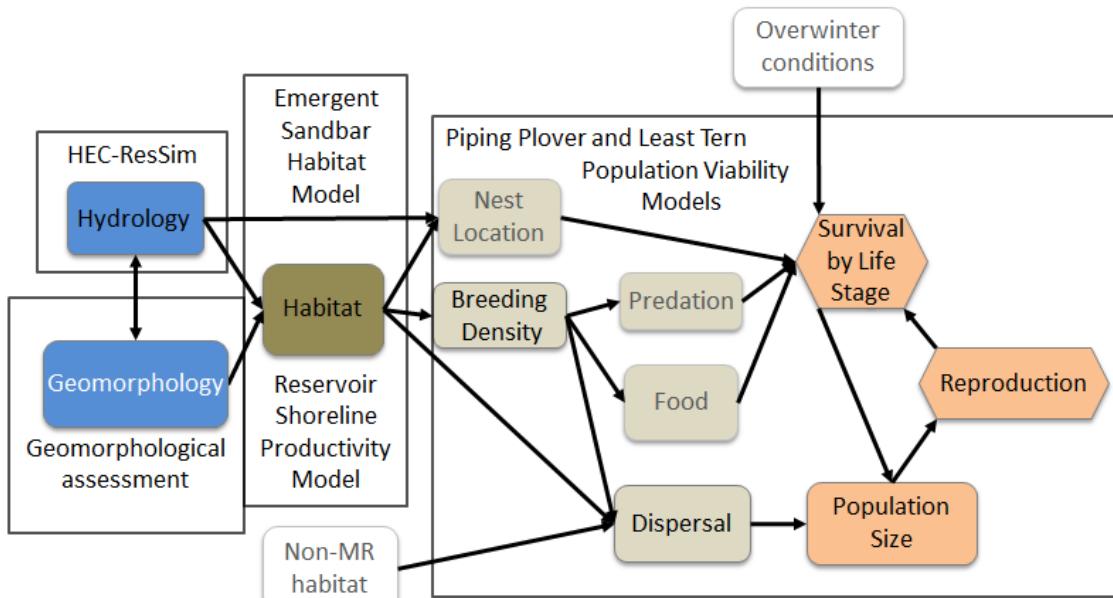

33 Hydrology and reservoir operations are modeled using HEC Res-Sim, which routes
34 basin runoff through the Missouri River using specified rules for reservoir operations.
35 These rules can be modified to reflect potential changes to reservoir operations, e.g. to

1 release flows capable of creating new sandbar habitat. Currently, the Res-Sim model
 2 uses historical runoff and depletions from 1930-2012 as inputs and provides reservoir
 3 elevations, dam releases, and river stage at selected locations as outputs. The model uses
 4 historical hydrological inputs to cover a range of natural variability in basin runoff.
 5 Those inputs are runs through a model of the modern hydrosystem with a consistent set
 6 of operation rules for each 50-year run.) Sequences of output with randomly selected
 7 initial years are used in the habitat models.

8

9 Figure 37. Overview conceptual ecological model (CEM) for plovers (see Appendix B for full set).

10

11 Figure 38. Quantitative model components in relation to conceptual model elements. Elements with black text
 12 are represented explicitly in the model; elements with gray text are represented implicitly.

1 Plover and tern sandbar habitat (emergent sandbar habitat, ESH) under varying flow
2 conditions is predicted using a model of the change in ESH due to vegetation growth
3 and the deposition and erosion of sandbars as a function of flow and ESH area. At low
4 flows, erosion rates are low. Net erosion is greatest at moderate flows, then, as flows
5 increase, net deposition begins to occur. Erosion is greater, at occurs at higher flows,
6 when the existing ESH area is larger. ESH models were based on a mechanistic
7 understanding of sandbar dynamics and parameterized for each of the three riverine
8 reaches individually based upon satellite imagery for all reaches and geomorphic studies
9 for Gavins Point Reach. They use initial ESH area and mean monthly river flows as
10 inputs. Output consists of the standardized acreage of ESH, set to a constant flow for
11 each reach (see Section 3.2.3 for specifications) and available acreage of ESH, adjusted
12 to the maximum July flow in each year to estimate ESH availability for nesting and
13 brood-rearing.

14 Reservoir shoreline habitat is modeled indirectly. Fledgling production on reservoir
15 shorelines is modeled as a function of two hydrological metrics: the vertical extent
16 (elevation range) of exposed shoreline that had been inundated for at least 160 days in
17 the past two years, and the increase in reservoir elevation during the nesting season.
18 These metrics predict observed fledgling productivity more effectively than estimates of
19 habitat area, which is challenging to quantify and predict on reservoir shorelines. The
20 reservoir habitat-productivity model uses the daily time series of predicted reservoir
21 elevations and breeding pairs as inputs and outputs the number of fledglings produced.

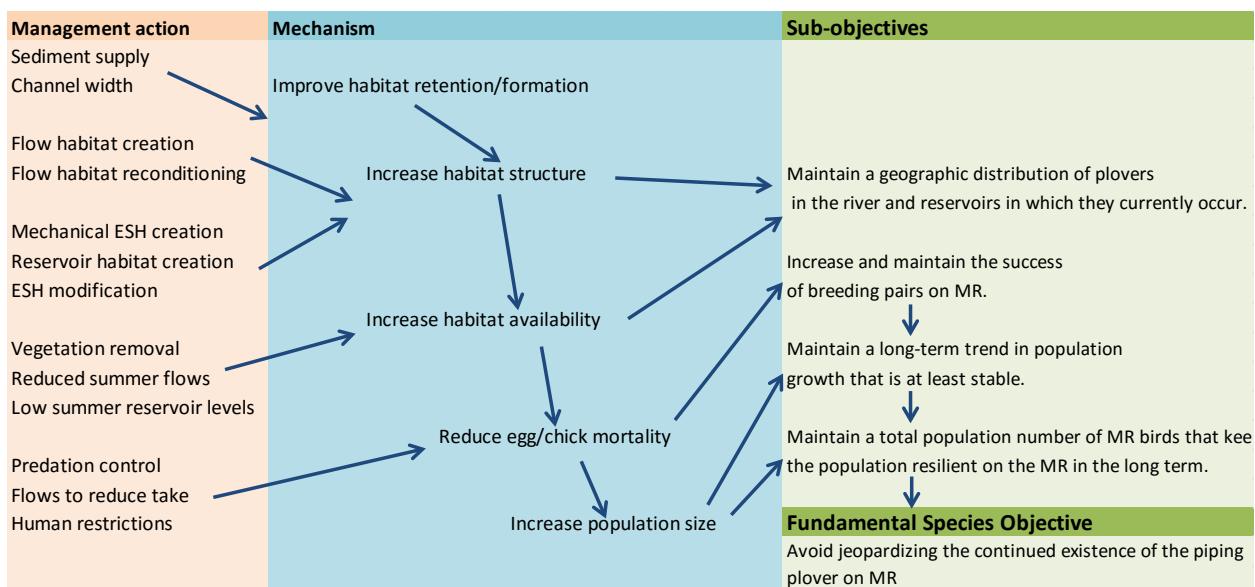

22 Plover and tern populations are modeled using species-specific population models that
23 account for the number of fledglings produced per pair of adults as a function of
24 population density on riverine habitat and hydrologic change on reservoir habitat,
25 annual survival for life stages (juvenile and adult plovers; juvenile, young adult and
26 older adult terns) and dispersal between river segments and regions. They use the
27 output of available ESH from the habitat models and reservoir shoreline fledgling
28 production rates as inputs and produce as outputs fledge ratios (# fledglings/pair of
29 adults), population sizes and population growth rates for each year and segment
30 simulated. The model assumes equal rates of immigration and emigration with other
31 breeding areas.

32 The habitat and population models include uncertainty about parameter estimates.
33 Hydrological variability is represented by sequences of years in the period of record
34 (1930-2012) with a randomly selected start year. The population models also include
35 demographic uncertainty (individually-drawn chances of individuals being born and
36 surviving each year), temporal variability (uncertainty in parameter values from year to
37 year, interpretable as environmental randomness due to factors other than flows) and
38 observation error. For any given scenario, models are run 5,000 times with random

1 variables to representing each type of uncertainty (Monte Carlo simulations). Results
 2 are presented as metrics reflecting the distribution of results, e.g. median and
 3 confidence intervals.

4 *3.1.2.4 Effects of management actions on plovers and terns*

5 The management actions evaluated in the EA affect bird populations through several
 6 mechanisms: by improving the retention and formation process for habitat, by
 7 increasing habitat structure, by increasing availability of existing habitat, or by reducing
 8 the mortality of eggs and chicks. The mechanisms have a cascading effect (Figure 39)
 9 such that actions that improve habitat structure or availability will, all other factors
 10 being equal, also reduce egg/chick mortality and thus improve population metrics.
 11 Consequently, if sufficient habitat is available, then less effort will be required on actions
 12 to directly improve egg and chick survival. The opposite is also true, such that a lack of
 13 habitat requires more intensive population protection in order to meet objectives.

14
 15 Figure 39. The management actions evaluated in the EA, their mechanisms for affecting habitat and species
 16 and consequent effects on the fundamental species objectives and sub-objectives.

17 A related finding of the EA is that management actions for plovers and terns are highly
 18 interdependent: both the opportunities for and effects of a given action depend on how
 19 much habitat is available, how dense the breeding bird populations are, and what other
 20 actions are taking place (see Section 3.5.4). Decision-makers must take a synthetic
 21 approach, considering the status of the system as a whole, the needs of the species, and
 22 the management opportunities before choosing a course of action, rather than making
 23 separate decisions about whether to implement specific actions (Sections 3.5.3 and
 24 3.6.1, for example). Quantitative models (Section 3.1.2.3) are fundamental to this

1 process, allowing for as many relevant factors to be taken into account as the current
2 state of knowledge allows.

3 3.1.2.5 *Hypotheses and uncertainties*

4 Bird management is made challenging by four sources of uncertainty:

5 1) **Environmental variability:** Future climate and weather cannot be known with
6 certainty. The greatest source of environmental variability for MR birds is basin
7 runoff and resulting system storage and flows, which are major drivers of habitat
8 availability. Local weather, including storms and high temperatures, also affect
9 reproduction and survival. This type of uncertainty is largely irreducible, though
10 advances in modeling can lead to better estimates of the likely distribution of future
11 conditions.

12 2) **Structural uncertainty:** While the fundamental relationship between hydrology,
13 habitat availability and reproductive success is supported by evidence described in
14 the EA, uncertainty remains about the functional form of some relationships. For
15 example: What is the shape of the relationship between flow, ESH area, and
16 sediment transport? What aspects of habitat quality affect fledgling production?
17 What factors best predict reproductive success on reservoirs? How are Missouri
18 River populations affected by metapopulation dynamics? Structural uncertainty can
19 be reduced through research, monitoring, and improvements to models.

20 3) **Parametric uncertainty:** Once the structure of relationships is known,
21 uncertainty remains about their strength. How much sand is eroded or deposited at a
22 particular flow? How much habitat is available at a given river stage? What is the
23 survival rate for birds during their first winter? How strongly does population
24 density affect chick survival? As with structural uncertainty, these uncertainties can
25 be reduced through research and monitoring and incorporated into models.
26 However, they may vary with time and location.

27 4) **Observation uncertainty:** Population and productivity surveys are not 100%
28 accurate. The degree of error and direction of bias can vary by habitat type,
29 conditions and level of effort, and thus tend to differ by location and year. The design
30 and level of effort in a monitoring program can reduce observation error and, in
31 some designs, estimate the error in the survey, which allows for more accurate use of
32 the resulting information.

33 All types of uncertainty affect the ability to make effective and efficient management
34 decisions, from uncertainty about future conditions (e.g., How much water will be in the
35 system? How many birds will survive and return to breed in specific locations?), to
36 uncertainty about effectiveness of management actions (e.g., How long will created
37 habitat last? How much foraging habitat will be available, and at what quality? How
38 much will predation be reduced by a planned level of control effort?)

1 While research and monitoring may increase certainty about of system dynamics, long-
2 term trends may decrease that certainty without ongoing or periodic updates. Changes
3 in climate can change hydrological trends and variability; changes in the sediment
4 budget will affect ESH dynamics. Stressors on the Missouri River, wintering habitat, or
5 nearby breeding areas that would affect productivity, survival, and/or dispersal may also
6 change over time. Ongoing or periodic assessments will be necessary to detect and
7 adjust to changing conditions.

8 The overarching scientific and management uncertainties for plovers and terns are
9 summarized in the following questions, which AM must seek to address.

10 **Overarching Critical Uncertainties**

- 11 • How much habitat is needed to maintain a resilient population of birds and how
12 should it be distributed in space and time?
 - 13 ○ How should habitat be quantified and what determines habitat quality?
 - 14 ○ What is the relationship between habitat quantity and quality and bird
15 productivity and success on river and reservoir habitat?
- 16 • How are the Missouri River populations of plovers and terns affected by migratory
17 and metapopulation dynamics?
 - 18 ○ How are conditions in overwintering habitats affecting the Missouri River
19 breeding populations over time?
 - 20 ○ How do habitat conditions in other breeding areas and dispersal to and from
21 those habitats affect the Missouri River breeding population over time?
- 22 • How will long-term changes in climate and channel morphology affect habitat and
23 species management?
 - 24 ○ How will climate affect hydrology including the timing, magnitude, and
25 variability of basin runoff and the frequency, intensity, and duration of
26 extreme events?
 - 27 ○ How will sediment dynamics change over time and affect the ability to create
28 and maintain habitat through various means?
- 29 • How can the bird AM program buffer against natural (especially hydrologic)
30 variability and uncertainty for long-term success?
- 31 • How can the bird AM program buffer against institutional and socioeconomic
32 variability and uncertainty for long-term success?

34 In addition to the overarching critical uncertainties, there are questions about
35 management approaches and specific management actions. Each management
36 action has a testable hypothesis about its mechanism and effectiveness. Table 19 lists
37 these uncertainties and hypotheses.

Table 19. Critical uncertainties related to bird management actions evaluated in the EA and associated management hypotheses.

Management Critical Uncertainties	Actions	Management hypotheses
Creating New Habitat What is the most effective and efficient way of creating habitat within the larger context of management and uses of the Missouri River?	Habitat-creating flows	Habitat-creating flows of sufficient magnitude and duration increase the area of nesting/brood rearing habitat and foraging habitat on the river by increasing deposition, assuming sediment is available, thereby increasing fledgling productivity.
a. Are there effective and implementable ways of using flow modification to provide and enhance habitat availability and quality?	Mechanical habitat creation on river (ESH)	Mechanical habitat creation of ESH in river segments increases nesting/brood-rearing and foraging area, which increases survival of eggs to chicks and chicks to fledglings by reducing predation and increasing food availability.
		Mechanical habitat creation of sandbars in river segments increases nesting/brood-rearing and foraging area relative to the condition and availability of habitat at other breeding areas, thus increasing the number of adults through net immigration from other areas.
b. Can habitat be mechanically created in an effective and sustainable manner?	Mechanical habitat creation on reservoirs shorelines or islands	Mechanical habitat creation of habitat on reservoir shorelines/islands increases nesting/brood-rearing and foraging area, which increases survival of eggs to chicks and chicks to fledglings by reducing predation and increasing food availability.
c. What are the effects of habitat creation actions on Human Considerations?		Mechanical habitat creation of habitat on reservoir shorelines/islands increases nesting/brood-rearing and foraging area relative to the condition and availability of habitat at other breeding areas, thus increasing the number of adults through net immigration from other areas.
	Mechanical creation of hydrologically-connected non-sandbar habitat on river segments	Mechanical habitat creation of habitat other than sandbars or in segments outside of the current ESH scope increases nesting/brood-rearing and foraging area, which increases survival of eggs to chicks and chicks to fledglings by reducing predation and increasing food availability.
		Mechanical habitat creation of habitat other than sandbars or in segments outside of the current ESH scope increases nesting/brood-rearing and foraging area relative to the condition and availability of habitat at other breeding areas, thus increasing the number of adults through net immigration from other areas.

Maintaining Existing Habitat To what extent can maintaining existing habitat contribute to population objectives compared to creating new habitat? a. Does maintained habitat improve habitat metrics and support production equivalent to new habitat? b. Can flow be used to maintain habitat without increasing net erosion?	Modification or augmentation of existing sandbars	Modification or augmentation of existing sandbars increases nesting/brood-rearing and foraging area, which increases survival of eggs to chicks and chicks to fledglings by reducing predation. Modification or augmentation of existing sandbars increases nesting/brood-rearing and foraging area, which increases food availability and chick survival to fledglings. Modification or augmentation of existing sandbars increases nesting/brood-rearing and foraging area relative to the condition and availability of habitat at other breeding areas, thus increasing the number of adults through net immigration from other areas.
	Vegetation removal (spraying/mowing) on river/on reservoir	Vegetation removal increases nesting/brood-rearing and foraging area, which increases survival of eggs to chicks and chicks to fledglings by reducing predation (by increasing area and by removing cover for predators). Vegetation removal increases nesting/brood-rearing and foraging area, which increases survival of chicks to fledglings by increasing food availability. Vegetation removal increases nesting/brood-rearing and foraging area relative to the condition and availability of habitat at other breeding areas, increasing the number of adults through net immigration from other areas.
	Habitat-conditioning flows	Habitat-conditioning flows are not of sufficient magnitude and duration to create new sandbars, but scour vegetation or deposit new sediment on existing bars, increasing the area of nesting/brood-rearing habitat, thereby increasing fledgling productivity.
Improving Availability of Existing Habitat To what extent can improving the availability of existing habitat through flows contribute to population objectives compared to creating new habitat?	Reservoir water level management	Declining reservoir water levels between years and/or steady or declining water levels during the nesting season increases the area of suitable nesting/brood rearing and plover foraging habitat on the reservoirs, thereby increasing fledgling productivity.
	Lowered nesting season flows	Lowered nesting season flows increase the area of suitable nesting and brood rearing habitat and foraging habitat on the river, thereby increasing fledgling productivity.
Population Protection To what extent can population protection actions positively contribute to the success of birds on the Missouri River?	Flow management to reduce inundation of nests and chicks	Steady or declining reservoir levels and/or river flows during the nesting season increases survival from egg to chick and chick to fledgling by reducing the risk of nest inundation and chick stranding and by maintaining or increasing foraging habitat.
	Predator removal	Predator removal increases survival of eggs to chicks and chicks to fledglings.
	Nest caging	Nest caging protects plover nests from predators, increasing survival of eggs to chicks, though survival of adults may be negatively affected by cages.
	Human restrictions measures (signs, barriers, education)	Human restriction measures reduce human activity on nesting and foraging habitat, increasing survival both by decreasing direct mortality and indirect effects on survival caused by stress.

1

2 3.1.2.6 *Implications for AM*

3 Managers on the MR must make decisions without limited knowledge of *what*
4 conditions will occur in the future that will affect both the habitat and species and the
5 ability to manage them, and *how much* those conditions will affect habitat, species, and
6 the effectiveness of management actions. Additional uncertainty remains regarding how
7 effective some management actions are. In comparison to pallid sturgeon, structural
8 uncertainty about bird dynamics—how key elements of the system relate to each other—is
9 relatively low, but the strength, and in some cases form, of those relationships is still
10 uncertain. If these uncertainties are not dealt with explicitly and thoughtfully during the
11 management process, management will be haphazard and inefficient at best, and
12 wasteful and ineffective at worst.

13 The role of AM for management of terns and plovers is to improve decision making in
14 light of uncertain future system state—an uncertainty that can never fully be resolved—and by improving understanding of how the system functions. The agencies retain
15 discretion and ultimately the decision making authority in determining how to address
16 this uncertainty; the AM Plan improves the process, information and understanding
17 surrounding the needed decisions.

19 The strong role of variable hydrology in driving plover and tern habitat and populations
20 (Buenau et al. 2014) compels a management program to adapt to accommodate
21 droughts and high flows, which affect both the need for action and the ability to act.
22 Simply reacting to these circumstances is not AM. Rather, AM requires that adjustments
23 be made according to the best available science, which is deliberately invested in and
24 improved upon as part of the AM program.

25 Management decisions for the birds can be improved with learning. Management
26 actions directed towards meeting habitat and bird objectives (passive AM) can add
27 valuable information to ongoing assessments of key processes and relationships if their
28 outcomes are monitored with sufficient and known accuracy. Natural variability
29 broadens the range of conditions for estimating relationships. Opportunities to manage
30 in a way to prioritize learning (active AM) by exploring management options where
31 uncertainty is higher and incorporating experimental design into management planning
32 will accelerate the learning process. For a long-term management program with high
33 resources use, deliberate intent to both learn and use the knowledge gained for
34 improved decision making can lead to significant efficiencies, lowered costs, and
35 improved likelihood of success.

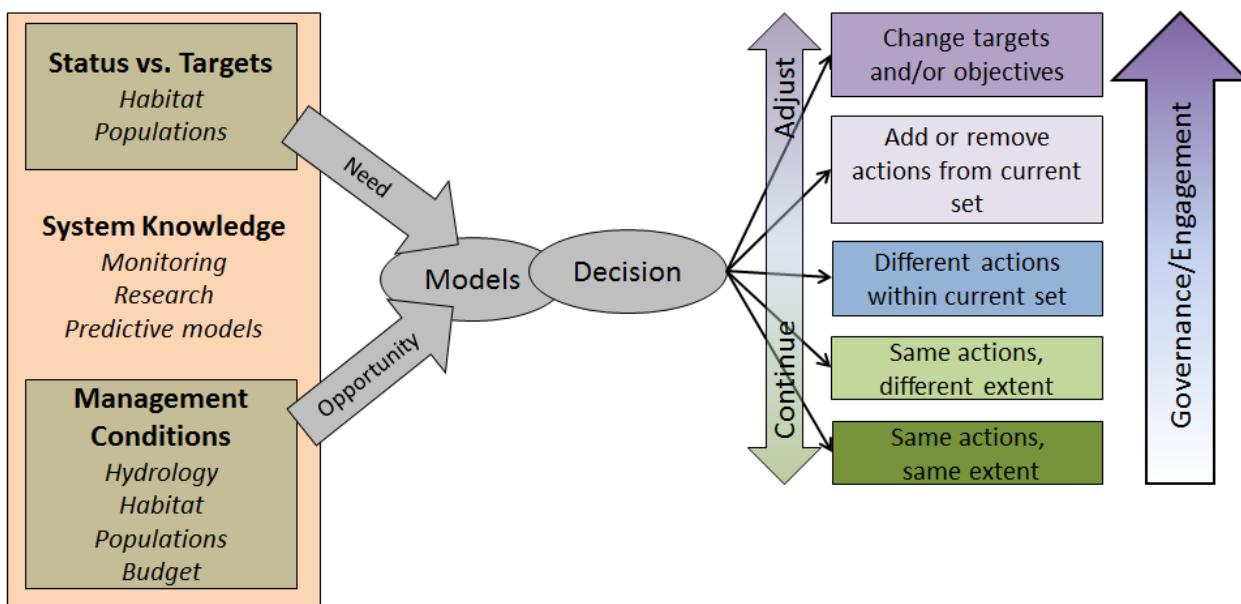

1 Models integrate learning in the AM process by both projecting the outcomes of
2 different management scenarios and summarizing and quantifying uncertainty. Models
3 can also be used to prioritize information needs and track the benefits of learning over
4 time. Hypotheses about the effects of management actions, developed in the EA (Section
5 3.1.2.5), are routinely confronted with new information during the AM process to
6 determine the level of support for the hypotheses, revise hypotheses, and develop new
7 ones if warranted.

3.2 Plan and Design

9 3.2.1 Bird Framework

10 The key decision-making information and range of decisions for bird AM is illustrated in
11 Figure 40. System status together with the management conditions affecting potential
12 actions provide the information needed to make decisions. That information is
13 interpreted in the context of the current understanding of the system, as synthesized by
14 models, to make decisions. Rather than a dichotomy of continue/adjust, as AM
15 decisions are often portrayed, decisions range from continuing the current activities
16 exactly, to continuing actions with adjustments, to changing the actions that are
17 implemented, to adjusting fundamental components of the program. As the breadth and
18 significance of decisions increases, the level of governance and stakeholder engagement
19 increases accordingly.

20 The variability of the MRMS and the need to balance multiple and, at times, competing
21 species and HC objectives support a toolbox approach to managing for plovers and
22 terns. The approach consists of having multiple flexible management actions and
23 options available to ensure effective management in a context of natural variability and
24 socioeconomic uncertainty. The set of actions initially in the toolbox and their
25 specifications will be determined by the USACE and USFWS in collaboration with
26 MRRIC. As the AM Plan is implemented, learning about actions is applied to use them
27 more effectively. Learning may also result in changes to the bounds and conditions
28 under which actions are applied, or the addition or removal of management actions.
29 Decisions to make changes are evidence-based and involve collaborative processes with
30 MRRIC when HC's are affected.

1

2 Figure 40. Factors affecting AM decisions for birds and the nature of those decisions

3 The “toolbox” concept is illustrated in Figure 41. The hypothetical set of actions (A-E)
 4 defined in the ROD is available for use. Within that set, several may be selected for use
 5 in a specific year (A, C, E), while others are not (B,D). Other actions may have been
 6 evaluated in the EIS but are not included in the ROD (F,G), or were not evaluated in the
 7 EIS (H,I); actions in either of these categories are not available for immediate
 8 implementation. Numbered arrows in Figure 41 indicate the range of AM adjustments
 9 that are possible:

- 10 4. Reduce the scope (e.g. location, magnitude, duration, timing) of future
 11 implementation of an action, most commonly because of the potential for adverse
 12 impacts if the action were implemented as currently specified (Section 2.4.6.6);
- 13 5. Increase the scope of future implementation of an action, to improve benefits if
 14 adverse impacts are found to not be a concern (Section 2.4.6.5);
- 15 6. Remove an action from future implementation because of insufficient positive effect
 16 or unacceptable negative effects (Section 2.4.6.6);
- 17 7. Change how an action is implemented (e.g. techniques and engineering design)
 18 without changing the scope;
- 19 8. Add an action that was evaluated in the EIS but not part of the ROD, for which the
 20 evaluation is still sufficient, requiring a decision document (Section 1.1.6) and, if
 21 necessary, adjustments to the Master Manual (Section 2.4.6.3 and Attachment 5);
- 22 9. Add an action that was not evaluated in the EIS, requiring additional NEPA analysis
 23 (Section 2.2.5). If findings are acceptable, adjustment 5 would be applied next.

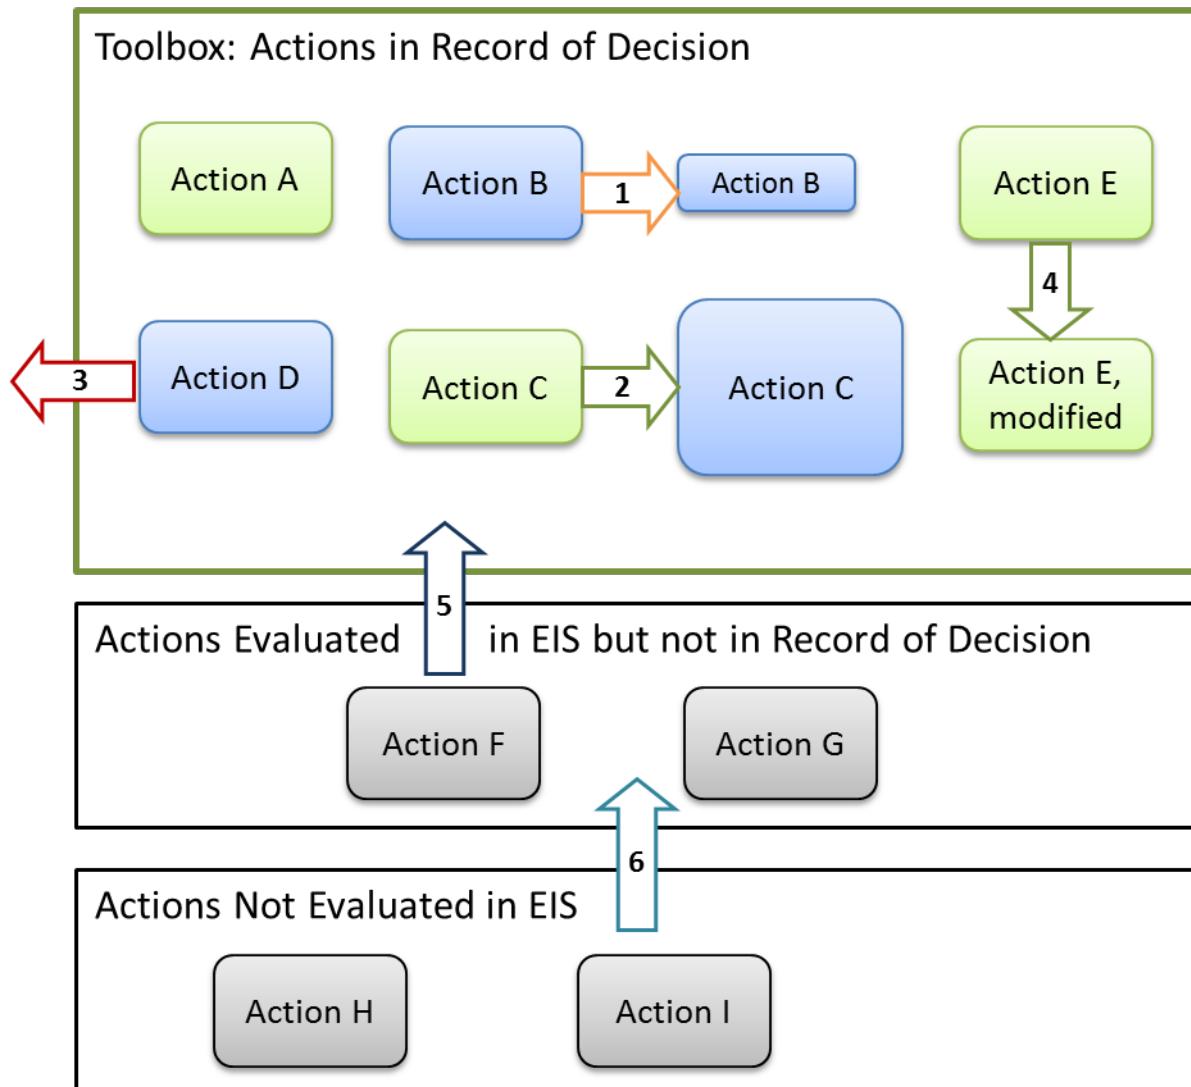

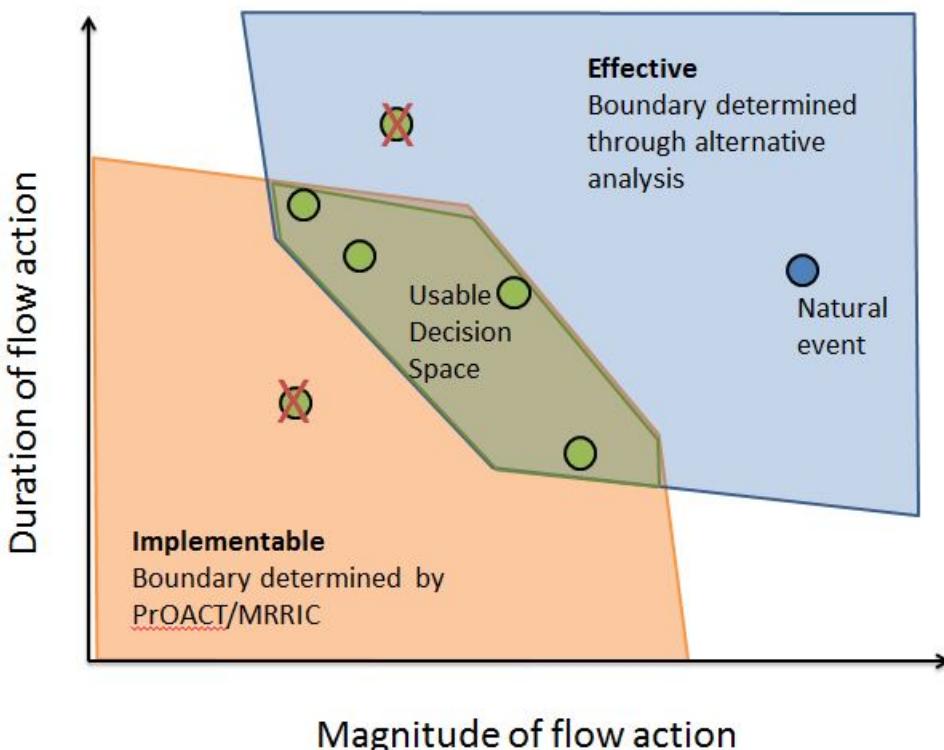

Figure 41. Illustration of “toolbox” concept for AM, indicating action status and a range of potential AM adjustments to actions. Green boxes (A,C,E) indicate actions implemented in a given year; blue boxes (B,D) indicate actions not implemented that year; gray boxes (F-I) indicate actions not currently implementable.

Bird management actions evaluated in the EIS have evidence for their effectiveness based on prior implementation and/or modeling. Other potential management actions were either screened from the EIS alternatives due to uncertainty about their effectiveness relative to impacts, not included in EIS alternatives due to feasibility or authority, not included in the scope of the EA, or identified after alternatives were formulated for the EIS. The AM process includes learning about management actions for which identifiable causal links suggest the potential for species benefits, even if those benefits and any corresponding impacts are not yet understood sufficiently for full implementation. As such, actions not in the ROD with some evidence for effectiveness are identified for research and possible pilot-scale implementation.

- 1 The pallid sturgeon AM framework identifies four levels of implementation (Section
2 4.2.1.1). Research or pilot-scale implementation for birds is analogous to Level 1 and
3 Level 2 actions for pallid sturgeon, respectively. Bird actions included in the ROD are
4 analogous to Level 4 actions in the sturgeon framework. Because ESH targets have been
5 established, there are no bird analogues to Level 3 actions in the sturgeon framework.
6 Additionally, while Level 1- and Level 2-type actions have been identified for birds,
7 research and implementation timelines have not been defined because of the identified
8 sets of Level 4 actions capable of reaching targets in all EIS action alternatives.
- 9 The decision space for an action is bounded by what is effective and what is
10 implementable (an example for a flow action is described graphically in Figure 42).
11 Determination of effectiveness is provided by the EA and subsequent assessments,
12 supplemented by learning from implementation. An action is deemed implementable
13 following collaboration with MRRIC and evaluation in the programmatic EIS or
14 subsequent NEPA analyses to determine the extent to which the action can be used. The
15 overlap of these regions is the usable decision space. If there is no overlap, the action
16 cannot be used unless adjustments to the boundaries are made.

- 17
18 Figure 42. Schematic of decision space using flow management for ESH creation
19 Actions can be implemented with any combination of parameters that fall within the
20 effective and implementable decision space (green circles.) Depending on circumstances

- 1 and opportunity, they may be below the upper bounds of what is implementable (e.g.
2 actions implemented at less than their full scope).
- 3 Implementation outside the usable decision space (green circles with red X's) is not
4 planned as part of species management as they are expected to either be ineffective or
5 have unacceptable levels of impacts. On occasion, events such as naturally high runoff
6 may occur that lead to reservoir releases outside of the decision space (blue circle.)
7 While not considered an action for habitat or species management, these are important
8 learning opportunities.
- 9 The bounds of the implementable and effective regions may be adjusted through AM. If
10 impacts are found to be greater or less than expected, the implementable bound may be
11 adjusted through collaboration with MRRIC (Sections 2.4.6.5 and 2.4.6.6). If
12 effectiveness is found to be greater or less than expected, the effective boundary would
13 be adjusted through the Science Update process (Section 2.4.3). These adjustments may
14 have the effect of increasing, decreasing, or eliminating the usable decision space.

15 **3.2.2 Metrics and management conditions**

16 Habitat and species metrics
17 contain the necessary
18 information to evaluate the
19 overall status of habitat and bird
20 populations on the Missouri
21 River and are directly related to
22 the objectives.

Note: the details of some metrics will depend on decisions about the monitoring program. Some redundancy may be included in the following list; though similar but distinct metrics have benefits for understanding the system, some may not be retained in future drafts.

23 **3.2.2.1 Habitat metrics**

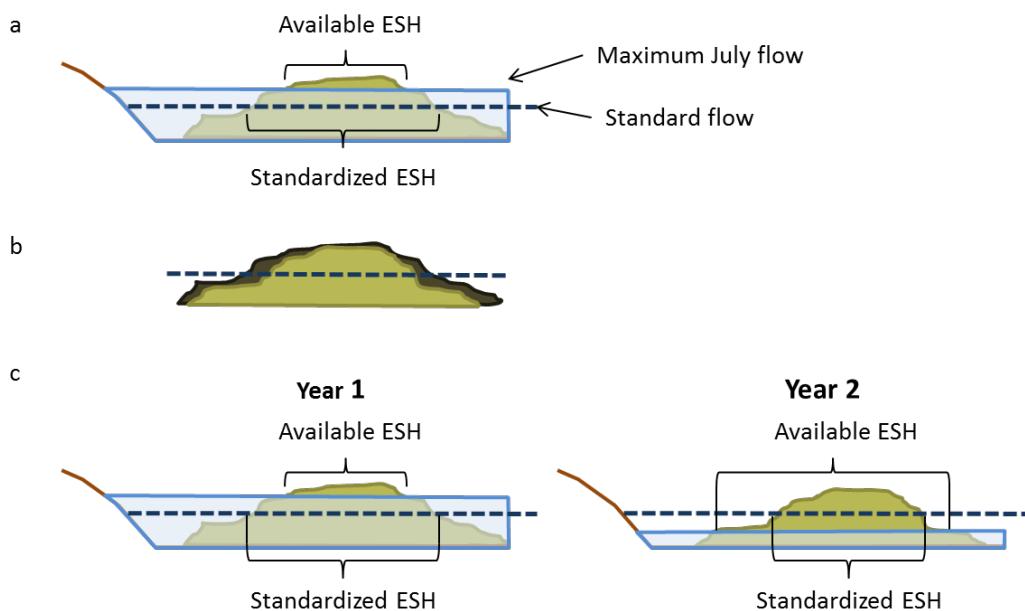

24 Emergent sandbar habitat acreage is estimated from satellite imagery acquired during
25 the nesting season. Wet or dry sand with less than 30% vegetation cover is delineated as
26 ESH. The area delineated from imagery will depend upon the flows occurring when the
27 imagery was acquired. To measure ESH in a consistent and meaningful way, the
28 delineated area is adjusted using discharge-area relationships to reflect area available at
29 two different flows:

- 30 1) **Standardized ESH (acres)** is the area above water if releases were 31.6 kcfs from
31 Gavins Point Dam, 30.5 kcfs from Fort Randall Dam, and 23.9 kcfs from Garrison

1 Dam¹. Estimating ESH acreage at constant flows each year allows for the detection of
 2 changes in sandbar structure due to erosion, deposition, construction, or mechanical
 3 modification.

4 2) **Available ESH (acres)** is the area above water during the maximum July release
 5 for each reach for the specified year. The acreage available at this flow is used to
 6 represent the limiting amount of habitat available during the brood-rearing season,
 7 when plover chicks are foraging. It reflects some of the effects of flow management
 8 during the nesting season.

9 Habitat quantification is binary; land cover is or is not classified as habitat, with no
 10 further distinction as to quality. The AM program will work to develop metrics that
 11 determine habitat quality as a function of sandbar form (e.g. elevation, cutbanks), land
 12 cover, and landscape characteristics (e.g. channel width, distance to trees) as
 13 appropriate. Habitat quality metrics will allow improved estimates of bird productivity
 14 and inform planning for habitat construction and modification actions and project
 15 design.

17 Figure 43. ESH characterization. a) Available ESH is measured at the maximum July flow (blue outline)
 18 observed in that year. Standardized ESH is observed at the same flow (dashed line) each year. b) Standardized
 19 ESH measures changes in sandbars due to erosion from an earlier year (dark profile) to a later year (light
 20 profile). c) Available ESH area may increase from one year to next if flows are lower, even though standardized
 21 ESH area decreases from erosion and vegetation growth.

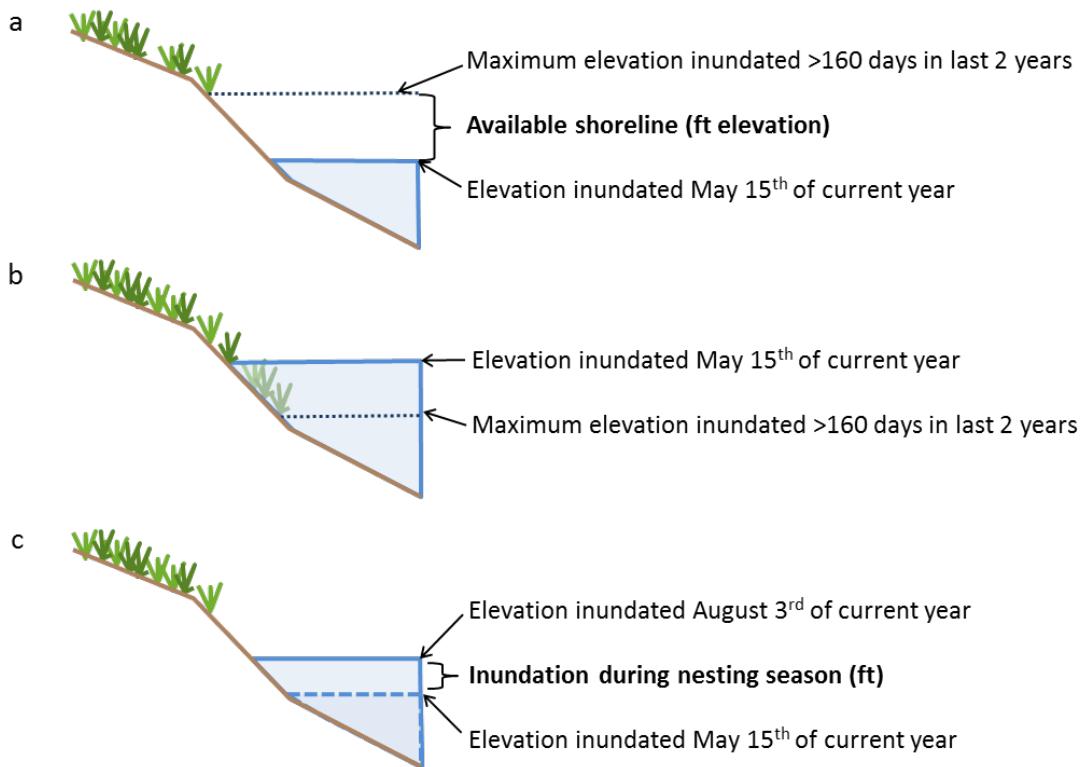

¹ The Gavins Point flow is based on releases from Gavins Point Dam needed to meet downstream flow targets during the July Median, Upper Quartile, and Upper Decile runoff conditions from the Master Manual. The flows for the other segments are based on an average of the July average daily outflows from 1967-2010. The choice of flows is somewhat arbitrary; what matters is that the same flows are used consistently through time and across models and metrics.

- 1 The EA found that fledgling productivity on reservoir shoreline habitats was best
2 estimated using two metrics that reflect the change in water elevation along the
3 shoreline between and during nesting seasons:
- 4 1) **Available shoreline (feet)** is the difference between the maximum shoreline
5 elevation that has been inundated for >160 days during the previous two years and
6 the shoreline elevation inundated on May 15th, the beginning of the current nesting
7 season. If the elevation on May 15th is higher than any elevation that has been
8 inundated >160 days in the previous two years, the metric is zero. This metric
9 estimates the relative amount of shoreline that has been inundated recently and for
10 long enough that it is free of vegetation. Because the shoreline slope varies, this
11 metric does not directly correlate to area¹.
- 12 2) **Inundation (feet)** is measured as the difference between the minimum and
13 maximum reservoir elevation during the nesting season. The difference is positive or
14 negative to distinguish between an increase in water levels during the season, which
15 might inundate nests, and a decrease, which typically provides more foraging area.
- 16 Available ESH and the two reservoir shoreline metrics were determined during the EA
17 to be the best available predictors of observed fledgling production. Targets have only
18 been specified for ESH, but tracking reservoir habitat metrics enables prediction of bird
19 productivity on reservoirs as part of overall population assessment.
- 20 3.2.2.2 *Species metrics*
- 21 Population monitoring provides metrics to describe the status of the population and
22 reproductive success:
- 23 1) **Population size**² estimated using one or both of the following techniques:
24 a. **Population size (number of adults)** is the number of adults observed on
25 riverine and reservoir habitat during the nesting season survey.
26 b. **Minimum breeding population estimate (pairs)** is estimated from the
27 daily sum of active nests plus all previously hatched nests plus nests failed
28 during incubation within the previous 5 days. It provides a minimum
29 estimation of pairs as not all nests may be detected.

¹ Habitat area was evaluated as a predictor of reservoir habitat productivity. Not only is habitat area on reservoirs difficult to quantify compared to riverine habitat, area did not predict productivity as well as the metrics defined here.

² Decisions yet to be made about the monitoring program will determine if total adult birds can be estimated, or only the breeding population. If the total number is available it will help determine if conditions have reduced the proportion of birds able to breed in a given year.

- 1 2) **Population growth rate**, λ , is the change in population size between years
 2 expressed as a ratio (N_t/N_{t-1}) and indicates whether the population is growing ($\lambda > 1$)
 3 or declining ($\lambda < 1$) and to what extent.
 4 3) **Fledge ratio** is the number of fledglings observed/(number of breeding adults/2).
 5 4) **Population density**¹ will be estimated as one or both of:
 6 a. The number of adult birds/available acres of ESH in a riverine segment.
 7 b. The number of breeding pairs/available acres of ESH in a riverine segment.
 8 All metrics are measured at the reach or reservoir scale and also reported at the region
 9 and system scale to provide a thorough understanding of system dynamics. Targets are
 10 defined at the region scale (Section 3.2.3).

11
 12 Figure 44. Shoreline habitat characterization. a) Available shoreline is measured as the difference between the
 13 maximum elevation inundated >160 days in the previous 2 years (dotted line) and the elevation inundated on
 14 May 15th of the current year (solid outline). b) If the elevation inundated on May 15th is higher than the
 15 maximum elevation inundated >160 years, the available shoreline metric = 0 ft. c) The inundation metric is the
 16 change in elevation between May 15th (dashed line) and August 3rd (solid line) and may be a positive number if
 17 water levels increase (shown) or a negative number if water levels decrease (not shown).

1 Decisions about the most effective means of monitoring population size may determine if only one of these metrics will be used, and which one. As with population size, breeding population density is the primary metric for estimating and tracking the relationship of fledgling production to habitat availability. If the monitoring program allows for the estimation of the total number of birds, total population density would help determine whether conditions are limiting nesting and not just nesting and brood-rearing success. Pending outcomes of monitoring program development, the same metric(s) will be estimated every year.

1 3.2.2.3 *Management Conditions*

2 The following metrics define opportunities and constraints for management actions in a
3 given year. There is some overlap with the habitat and species metrics, but all are listed
4 below to explain their applications.

- 5 1) **Standardized ESH (acres) and distribution** affect the outcome of flow
6 modification actions. How much sand flows erode or deposit is partly a function of
7 existing sandbar area. The effects of nesting season flows on habitat availability also
8 depend on the structure of existing ESH. The location of existing sandbars will also
9 determine where new sandbars can be mechanically constructed and whether
10 existing sandbars can be augmented or modified to improve quantity or quality of
11 ESH.
- 12 2) **Vegetated sandbar area (acres)** determines the potential and extent of
13 vegetation removal as a management action. The age of vegetation affects the
14 methodology for removing vegetation and the outcome. The extent of vegetation on
15 sandbars also affects predation risk, erosion rates, and potential for scour.
- 16 3) **Storage in reservoirs (million acre-feet) and planned releases (cfs)**
17 determine whether water is available for flow management actions and the possible
18 range of nesting season flows. Increased reservoir releases during ESH construction
19 or vegetation management seasons will affect the opportunity to implement those
20 actions.
- 21 4) **Tributary flows (cfs) and downstream stage (feet)** determine downstream
22 effects of reservoir releases, thus influencing both routine flow management and
23 flow modification actions. Unlike system storage, which changes slowly and
24 relatively predictably, tributary flows and river stage may change abruptly due to
25 precipitation events and thus cannot be forecasted very far in advance.
- 26 5) **Breeding population density (breeding adults/acre)** influences the need for
27 habitat creation and predation management. If ESH availability is low but
28 populations are small, less additional habitat is needed in the short term than if
29 populations are large. Higher population densities attract predators, increasing
30 proportional impacts on the bird populations. Predation management, particularly
31 predator removal, is more practical to implement when birds are constrained to nest
32 in limited areas.
- 33 6) **Budget (\$)** determines the extent to which management actions can be
34 implemented. Mechanical habitat construction and modification are most likely to
35 be constrained by budget, but other management, monitoring, and research
36 activities may also be constrained. The budget category also captures the effects of
37 other logistical constraints that might only indirectly affect costs (e.g. contractor
38 availability).

1 3.2.2.4 *Timing*

2 The utility of information for decision making depends upon its availability and
3 timeliness (see Section 0). Hydrological information (system storage, stage) is available
4 on a near-real-time basis. Other information is collected only periodically and model
5 projections may be needed during the decision-making process. ESH imagery is
6 acquired during the nesting season but must be processed prior to providing acreage
7 estimates. The processing step requires 3-5 months to complete for all reaches.
8 Population metrics are available in the fall once monitoring data has been compiled and
9 reviewed for quality. Decisions made for upcoming years (Section 2.4.2) are based upon
10 habitat and population information from two years prior to the year being planned for
11 (e.g. information about habitat present in FY20 would be used in FY21 to determine the
12 amount of construction planned for FY22; see Section **Error! Reference source not**
13 **found.**). Projections can be made using observed and/or predicted flows to estimate
14 ESH availability and other conditions for the upcoming or in-progress season.

15 **3.2.3 Targets**

16 Habitat and demographic targets for piping plovers, as specified by the USFWS (USFWS
17 2015, Buenau 2015), are described in this section. Because of the greater ESH acreage
18 needs for piping plovers which defend territories for nesting and foraging, compared to
19 colonially-nesting least terns, the USFWS has determined that meeting the plover
20 habitat targets will also fulfill habitat needs for least terns on the Missouri River¹.
21 Therefore habitat targets for least terns have not been specified at this time.

22 Pending the delisting process for the least tern, conservation plans will be developed for
23 the least tern under an ESA section 7(a)1 consultation process. The plan will include
24 post-delisting management commitments. Should management commitments result in
25 quantitative demographic targets for least terns, they will be added to the AM Plan. The
26 USACE monitoring program will continue to monitor and record least tern metrics as
27 per the USFWS post-delisting monitoring plan protocol (in development).

28 Targets are organized by sub-objective, each of which are necessary to ensure the
29 fundamental objective is met. A description of how the EA models were used to develop
30 targets and related analyses can be found in Buenau (2015). Additional information
31 about how targets will be used in decision making is found in Section 3.6; Section 3.6.5
32 outlines decision processes for when targets are not met.

¹ As terns and plovers do not compete for food or use the same habitat for foraging, there are typically not conflicts between nesting plovers and terns, and they have not been observed to compete for space.

1 **Fundamental Objective:** Avoid jeopardizing the continued existence of the
 2 piping plover due to the USACE actions on the Missouri River.

3 **Sub-objective 1 (Distribution):** Maintain a geographic distribution of plovers in the
 4 river and reservoirs in which they currently occur in both the Northern Region
 5 (Missouri River from Fort Peck Lake, Montana to Fort Randall Dam, South Dakota,
 6 including reservoir shorelines) and Southern Region (Missouri River from Fort
 7 Randall Dam, South Dakota to Ponca, Nebraska)¹.

8

9 **Means objective:** Meet sub-objectives 2, 3, and 4 in both the Northern and
 10 Southern regions.

11

12 **Sub-objective 2 (Population):** Maintain a population of Missouri River piping
 13 plovers with a modeled 95% probability that at least 50 individuals will persist for at
 14 least 50 years in both the Northern and Southern Regions.

15

16 **Means Objective (ESH):** Provide sufficient ESH (in-channel riverine habitat) on
 the Missouri River to meet the persistence target.

17 **Metric:** Number of standardized and available ESH acres measured annually.

18 **Target:** From Table 2 in this document:

		Acres of Emergent Sandbar Habitat					
		Northern Region			Southern Region		
		2.5%ile	Median	97.5%ile	2.5%ile	Median	97.5%ile
Standardized ESH Acres		200	428	1996	264	782	3907
Available ESH Acres Exceeded for Percentage of Years	75%	140	210	470	280	370	700
	50%	380	630	1000	460	720	1580
	25%	770	1420	2010	780	1370	3285
	10%	1340	2230	3625	1130	2320	5275

19

20 **Timeframe:** Median standardized ESH targets (428 acres in the Northern Region;
 21 782 acres in the Southern Region) must be met for 3 out of 4 years. Median available
 22 acres must be met or exceeded for the specified percent of years over a running 12-year
 23 interval.

¹ These regions correspond with two regions (Northern Rivers and Southern Rivers) of the four identified in the *Draft Revised Recovery Plan for the Northern Great Plains Piping Plover* (USFWS 2016). The Southern Region as referred to in this document, however, only refers to the Missouri River mainstem components and not tributaries.

1 **Sub-objective 3 (Population Dynamics):** Maintain a stable or increasing long-term
2 trend in population size in both regions.

3 **Metric:** Population growth rate (λ): the ratio of population size N between
4 the current year and previous year (N_t/N_{t-1}); calculated annually.

5 **Target:** $\lambda \geq 1$

6 **Timeframe:** The growth rate target must be met as a 3-year running geometric
7 mean¹ calculated as the cube root of the product of the growth rates for each of the three
8 years (i.e. $(\lambda_1 * \lambda_2 * \lambda_3)^{1/3}$).

9 **Sub-objective 4 (Reproduction):** Maintain fledgling production by breeding pairs
10 sufficient to meet the population growth rate objectives within both the Northern
11 and Southern Regions on the Missouri River.

12 **Metric:** Fledge Ratio: Number of fledglings observed/(number of breeding
13 adults/2), calculated annually.

14 **Target:** ≥ 1.14 chicks fledged per breeding pair.

15 **Timeframe:** The fledge ratio target must be met as a 3-year running arithmetic
16 mean.

17 If some or all of the targets are not met over the defined timeframes, a process to
18 determine the cause of the shortfall and identify potential remedies is defined in Section
19 3.6.5. Note that while the inability of the program to meet targets may lead to
20 reinitiation of Section 7 formal consultation with the USFWS, this occurs at the
21 discretion of the USFWS and after the process described in Section 3.6.5 has been
22 followed.

23

¹ The 3-year geometric mean is defined as the n^{th} root of the product of n numbers and is the appropriate calculation to describe the average of proportional metrics such as λ . The more familiar arithmetic mean, $(\lambda_1 + \lambda_2 + \lambda_3)/3$ would overestimate the actual population growth over the three-year period.

1 3.2.3.1 Notes on derivation and application of targets

2 3.2.3.1.1 *How targets were derived*

3 Hydrological, ESH, and plover population models were used to develop ESH targets.
4 The suite of models was run for 50 years with 5,000 replicates for each trial. The trials
5 assumed an ESH target for each reach to be met by annual ESH construction until an
6 amount of ESH was provided that resulted in meeting the population objective: less
7 than a 5% ($\pm <0.1\%$) risk of dropping below 50 individuals at any point in the 50 years,
8 within either of the two regions. Modeled hydrology based on basin runoff and
9 depletions from the period of record of 1930-2012 was used under reservoir operating
10 rules from the 2006 Master Manual; i.e. no flow modifications to create ESH. High
11 flows within those operating rules that created ESH (e.g. 1997, 2011) were included and
12 resulting ESH contributes to the targets. Fifty-year sequences of modeled reservoir
13 releases over the period of record with random start years were used for each model
14 replicate. A full description of the models used is provided in Buenau et al. (in prep).
15 Model runs for targets are described more thoroughly in Buenau (2015).

16 ESH targets have been provided rather than plover population targets. Because of the
17 dynamic nature of both riverine and reservoir habitat availability, long term (> 10-20
18 year) population persistence is driven much more strongly by habitat availability than
19 by population size. That is, a relatively large population is unlikely to persist if sufficient
20 habitat is not available in the long run. Smaller populations can persist and grow to
21 larger sizes if sufficient habitat is available most years. If sufficient habitat is provided,
22 population viability after 50 years is similar across a range of initial population sizes.
23 Note that this does not indicate that population size is not important for populations in
24 the short term as small population remain more likely to become very small or be
25 extirpated if faced with several bad years or consistently inadequate habitat. A single
26 target population size is difficult, if not impossible, to derive for multi-decadal
27 persistence goals. If sufficient habitat is provided, population numbers are not expected
28 to become small, and small populations should be able to rebound once habitat is
29 provided. If populations become small despite sufficient habitat availability,
30 identification of causes for unexpected outcomes (Section 3.5.11) is necessary to
31 determine if other management actions are required to avoid jeopardy to the species.
32 Further explanation and exploration of the use of habitat acres rather than population
33 size is also included in Buenau (2015).

34 3.2.3.1.2 *Role of reservoir habitat and other habitat types*

35 While targets for reservoir shoreline habitat availability have not been specified, plovers
36 nesting on reservoir shorelines are included in the modeling to develop ESH targets.
37 Reservoir conditions and resulting plover productivity on shorelines influence the

1 population viability in the Northern Region and thus the amount of ESH determined to
2 be necessary on the Garrison Reach to meet viability targets. That is, bird populations
3 on the reservoir count towards meeting the ultimate goal of population persistence.
4 Good nesting conditions on the reservoirs reduce the amount of ESH required to meet
5 population persistence targets. The current targets assume no significant changes to
6 reservoir operations from the 2006 Master Manual. If reservoir operation rules change
7 in a way that improves nesting conditions on the reservoirs and thus population viability
8 in the Northern Region, targets should be recalculated to accommodate the changes and
9 give “credit” to management actions that improve reservoir habitat. Conversely, if
10 reservoir operations become more limiting to fledgling production, targets should be
11 recalculated to ensure sufficient riverine habitat is available to support the population.

12 The habitat targets defined within this document are specifically for in-river ESH. If at
13 some point birds use habitat types other than ESH as defined in this document or
14 reservoir shorelines, and/or management actions involving the creation of other habitat
15 types are broadly implemented (i.e. beyond pilot projects following determination of
16 effectiveness), additional means objectives and associated metrics and targets for Sub-
17 Objective 2 will be developed.

18 When evaluating demographic metrics (population growth rate and fledge ratio), birds
19 nesting on reservoirs will be included. Evaluation of system state (see section 3.5.2) will
20 include calculation of population metrics on both reservoirs and the riverine segments
21 as well as the regions and river as a whole to understand system dynamics and guide
22 management decisions. Good nesting conditions on the reservoirs can offset poor
23 conditions on the river, and vice versa, in order to meet targets. The status of the
24 populations is evaluated holistically; if populations are doing well and expected to
25 continue to do well even if ESH acreage is below the median target, less focus will be
26 placed on ESH construction and targets may be recalculated to address the current
27 conditions. However, it is important to recognize that responses of plover populations to
28 changes in habitat availability may lag in time by one or several years; the lack of an
29 immediately apparent response to ESH availability dropping below target does not
30 indicate targets are inaccurate.

31 3.2.3.1.3 *Time frame requirements*

32 Standardized targets are required to be met 3 out of 4 years. This frequency was
33 calculated based on the proportion of time standardized ESH was above target in the
34 model runs used to calculate the target values. A moving window of 12 years is used for
35 available ESH. This allows for calculation of the exceedance probabilities over a
36 meaningful time frame, long enough to accommodate naturally occurring periods of
37 drought and high runoff that affect ESH quantities.

1 Three-year time frames were specified for the growth rate and fledge ratio parameters.
2 These moving averages allow for brief periods of lowered productivity or population
3 growth (e.g. high-water years that limit or preclude nesting; poor conditions on winter
4 habitat that reduce overwinter survival and population size). At the same time, they are
5 short enough to be responsive to management actions and provided indication of
6 potential problems in time to intervene. Other time frames could be considered if the 3-
7 year interval is found inadequate for supporting management decisions.

8 3.2.3.1.4 *Use of fledge ratios to measure productivity*

9 Fledge ratios are used to measure productivity rather than simple counts of fledglings.
10 Fledgling numbers are valuable information, but must be understood in the context of
11 the number of adult birds nesting on the MRMS. For example, 200 fledglings produced
12 by 200 adults would produce a fledge ratio of 2, which indicates excellent potential for
13 population growth and that habitat is not limiting the population. The same 200
14 fledglings produced by 600 nesting adults would produce a fledge ratio of 0.67, which is
15 not sufficient to support a stable or growing population and suggests that habitat may be
16 limiting reproductive success. The use of fledge ratios to measure productivity versus
17 measuring nest success and chick survival is a topic of continued discussion.
18 Considerations include accuracy, cost, disturbance and feasibility of monitoring to
19 acquire the necessary information to use one or more of these metrics to sufficiently
20 estimate breeding success on Missouri River habitats.

21 Fledge ratio targets were derived from the population models. The relationship between
22 the fledge ratio for a given year and λ the following year over a number of model
23 scenarios was used to calculate a fledge ratio that, on average, corresponded with $\lambda = 1$
24 (a stable population.) Thus the target fledge ratio is an estimate of the fledgling
25 production per pair required to support a stable population. By meeting or exceeding
26 this fledge ratio, the population would be expected to remain stable or grow,
27 respectively, other factors remaining equal. These targets are minimum values; if
28 population density is low, higher values are to be expected and necessary to support a
29 stable or growing population.

30 Targets for ESH and fledge ratios are dependent upon current system knowledge, as
31 synthesized in the hydrology, habitat, and population models, and upon current
32 conditions including climate, sediment supply, reservoir management practices, and
33 conditions in wintering habitat. As knowledge increases and/or conditions change, the
34 targets described in the AM Plan will likely no longer accurately reflect ESH amounts
35 and demographic rates necessary to meet population viability goals. Target values
36 should be updated periodically or following significant changes to models or conditions
37 (see Section 3.6.5)

1 3.2.3.2 *Incidental Take*

2 Incidental take consists of harm or harassment to threatened or endangered species that
3 may occur during an otherwise lawful activity that is not the purpose of the activity. In
4 the context of the MRRP, incidental take refers to negative effects upon plover
5 reproduction and survival caused by system operations to serve authorized purposes
6 and implementation of the actions described in the MRRMP-EIS and AM Plan. The
7 USFWS generally recognizes that some incidental take is anticipated, but that the
8 USACE will seek to minimize such take. Included in the issuance of a new Biological
9 Opinion, the USFWS will provide an Incidental Take Statement that will include a
10 statement of anticipated incidental take and reasonable and prudent measures, with
11 accompanying terms and conditions, to minimize take. When the statement is available,
12 the AM plan will incorporate the requirements and appropriate considerations related
13 to monitoring and implementation.

14 **3.2.4 Management Actions**

15 Management actions for birds serve three general functions: 1) create habitat with
16 construction or flows, 2) improve habitat quality or availability through construction,
17 modification, or flows, or 3) directly protect nests, chicks, and/or adults to improve
18 survival. A set of potential actions for birds was identified and evaluated in the EA.
19 Those actions, and several additional actions identified since the initial EA process, are
20 listed with their associated critical uncertainties and management hypotheses in Table
21 19. As described in Section 3.2.1, a subset of these actions were evaluated as part of
22 management alternatives in the DEIS. Some actions were included in all alternatives,
23 while others were included in only one of the 6 alternatives.

24 A preferred alternative has been identified for the DEIS and a selected alternative will be
25 described in the ROD. (This process is described in Section 2.2.5). This version of the
26 AM Plan reflects the determination of a preferred alternative but not the ROD. As the
27 set of actions selected for implementation may change prior to the ROD or during AM
28 following the ROD, this document retains the broader set of management actions and
29 associated decision criteria. They are organized into three sections within this
30 document:

- 31 1) Actions that have been evaluated in the EIS and identified as part of the Preferred
32 Alternative. If included in the ROD they would be available for full
33 implementation.
34 2) Actions evaluated in the EIS but not identified as part of the Preferred
35 Alternative. Following the ROD, this section will include actions in the EIS not
36 included in the Selected Alternative. They would not be available for full

- 1 implementation after the ROD, but may be explored through research and pilot-
 2 scale implementation.
- 3 3) Actions not evaluated in the EIS. They would not be available for full
 4 implementation after the ROD, but may be explored through research and pilot-
 5 scale implementation. These actions would need supplemental programmatic EIS
 6 analysis if later chosen for full implementation.

7 Table 20 summarizes how the bird management actions have been addressed in the EIS
 8 and how they are organized in this chapter.

9 Table 20. Summary of management actions for birds, their primary mechanism, whether they have been
 10 evaluated for the MRRMP-EIS and in which alternatives, and whether or not they have been included in the
 11 preferred alternative in the DEIS. References to the section of this document in which the action can be found
 12 are also listed.

Action	Function	Evaluation in EIS	In Preferred Alternative?	Section
Sandbar construction in river channel	Create habitat	Yes; all alternatives	Yes	3.2.4.1
Sandbar augmentation and modification	Create habitat; Improve habitat quality			
Vegetation management	Improve habitat quality			
Flow management to avoid take	Population protection			
Predation management	Population protection			
Human restrictions measures	Population protection			
Habitat-forming flow release (fall)	Create habitat	Yes; Alternative 5	No	3.2.4.2
Habitat-forming flow release (spring)	Create habitat	Yes; Alternative 4, 2*, 6*		
Lowered nesting season flow	Improve habitat availability	Yes; Alternative 2**		
Reservoir habitat creation (shoreline)	Create habitat	No	No	3.2.4.3
Reservoir habitat creation (island)	Create habitat			
Habitat creation connected to river channel	Create habitat			
Reservoir water level management to provide/improve shoreline habitat	Improve habitat availability			

13 *The spawning cue flows in Alternatives 2 and 6, while not designed to create ESH, may create some ESH in the
 14 spring when conducted, depending on magnitude and duration.

15 **Evaluated based on the flows prescribed in the USFWS 2003 Amended Biological Opinion, not based on outcomes
 16 of the Effects Analysis.

- 1 3.2.4.1 Actions and Decision Criteria for Full Implementation (*Included in Preferred*
- 2 *Alternative in the DEIS)*

Note: Some decision criteria have yet to be specified and are being developed through the collaborative process. Where criteria are not final, examples are provided, enclosed in “< >” in this draft. Further analyses, comments from the EIS review process, and deliberations among the agencies and MRRIC will be used to establish the criteria initially implemented under the AM Plan.

- 3 The actions described in this section have been evaluated in the MRRMP-EIS and included in the preferred alternative. If included in the ROD they will be available for program-wide implementation. Actions in this section are analogous to Level 4 actions as described for pallid sturgeon (Section 4.2.1.1).

- 7 3.2.4.1.1 *Sandbar construction*

- 8 **Definition and function:** Sandbar construction creates in-channel ESH using dredges and earth-moving equipment to provide nesting habitat. Sandbars are constructed to the desired condition including foraging habitat at a range of river stages.

- 11 **Implementation criteria:** The predictive ESH model is used to determine how many acres of sandbar habitat are needed to meet the standardized ESH target with a 60% chance of remaining above the median standardized ESH target for the next 2 years. If existing ESH is above the target, construction will begin if the acreage is expected to drop below target in the next 2 years. If logistics or funding does not allow for all necessary construction, river segments with higher plover population densities and lower fledge ratios and/or population growth rates will receive priority. Planning for construction on Garrison Reach will also consider current and expected conditions and productivity on the reservoirs; a more robust river sub-population may be required to support the northern region population objective if reservoir sub-populations are doing poorly. Model predictions of a range of options should be used to determine the best expected outcome for construction allocation.

- 23 Sandbars can be constructed in the spring after ice melts and before birds arrive in early May, or in the fall, after all birds have left and before ice forms (September through October or November.) To avoid inefficiencies, ESH should not be constructed in the season prior to a planned flow release to create habitat.

- 27 ESH construction sites are identified and prioritized using the ESHERs spatial decision support system tool developed by ERDC. Potential sites are selected and prioritized using three general criteria: avoidance of sensitive resources, utilization of areas of

1 natural sand accumulation, and nesting history of terns and plovers. Staging areas must
2 be available nearby, and may incur additional costs. Attachment 6 of Appendix G
3 provides further description of the ESHERs tool.

4 **Constraints:** Flows should be less than 35 kcfs for construction to be practical and
5 effective. Sandbars should be located in areas where flow velocity and resulting erosion
6 are expected to be low; depending on the extent and locations of existing ESH, vegetated
7 bars, and islands, highly suitable sites for new construction may become limiting.
8 Additional practical and regulatory constraints may apply, depending on location.

9 **Performance metrics:** Acreage of standardized and available ESH on constructed
10 sandbars over time is used to track total area and sandbar longevity. Nesting site
11 selection and fledge ratios are used to assess the effectiveness of constructed habitat and
12 its contribution to overall population dynamics. Metrics for nesting vs. foraging habitat
13 and overall habitat quality will developed under the AM Plan.

14 **Human considerations metrics:** Metrics for assessing whether constructed ESH
15 has any impact on HC interests, particularly as relates to localized flooding, ice jam
16 formation, bank erosion and localized scour and deposition of sediments are under
17 consideration. The AM Team and agency technical specialists engaged in a screening
18 exercise to identify concerns and potential monitoring and assessment needs related to
19 those concerns. The HC Team will, as its central charge, make recommendations for
20 monitoring needs and priorities as part of the WP development process (see Section
21 2.4.4). Those deliberations will help determine which metrics may be employed.

22 **Uncertainties, research and active AM:** Previous research and monitoring has
23 provided substantial evidence for the general suitability of constructed sandbars for
24 plover and tern nesting. The amount of habitat needed to support resilient bird
25 populations (ESH targets) and the rate it must be created are uncertain. Improvements
26 in ESH and bird modeling, supported by research and monitoring, will result in more
27 accurate estimates (see Section 3.3.7 for examples).

28 While the amount of habitat is known when ESH is created, habitat longevity and
29 quality over time is uncertain, both scientifically and because of variable conditions
30 (flow, wind and ice scour). How to most efficiently and effectively construct sandbars
31 can be answered through tests of different approaches and assessments of related
32 performance metrics (Table 21). At minimum, annual evaluations of habitat and bird
33 productivity should incorporate information about sandbar size, form, and landscape
34 context. Sandbars deliberately constructed with a range of characteristics will increase
35 the potential for learning about optimal project design. Experimental design of sandbars
36 should include at least 3 years of monitoring of treated and control sites.

1 Table 21. Questions and study summaries for ESH construction research and active AM.

Question	Study Summary	Metrics	Related studies
Management Uncertainty: What is the most effective and efficient way of creating habitat within the larger context of management and uses of the Missouri River?			
Associated Hypotheses: Mechanical habitat creation increases nesting/brood-rearing and foraging area, which increases survival of eggs to chicks and chicks to fledglings by reducing predation and increasing food availability. Mechanical habitat creation increases nesting/brood-rearing and foraging area relative to the condition and availability of habitat at other breeding areas, thus increasing the number of adults through net immigration from other areas.			
How large should sandbars be? Are single large sandbars or several small more effective?	Construction of one large and one or more small sandbars during the same year, controlling for as many landscape and location factors as possible.	ESH area, foraging habitat and nesting habitat area, # adults, # fledglings.	Assess effect of sandbar area on productivity with historical sandbars; control for age, vegetation, landscape features.
What ratio of nesting to foraging habitat is necessary to support successful productivity?	Construction of sandbars of similar size but different nesting/foraging habitat ratios during the same year.	ESH area, foraging habitat and nesting habitat area, # adults, # fledglings.	Assess historical sandbar edge/area and other metrics and site selection/fledgling production.
Where should sandbars be constructed relative to other sandbars used for nesting?	Construct new sandbars of similar size and design during the same year at a range of distances from sandbars currently used for nesting.	Site fidelity, adult and nest density, movement between sites, probability of human disturbance.	Assess use of historical sandbars relative to distance from other sites used for nesting.
Where should constructed sandbars be located relative to landscape features?	Construct new sandbars of similar size and design during the same year at different distances from key landscape features, including distance to trees, width of river, distance from the dam.	ESH area, # adults, # fledglings, predation rates, probability of human disturbance.	Assess use of historical sandbars relative to distance from landscape features.
Is adequate substrate currently available for creating sandbars? Does enough coarse material remain to support creation of new habitat? Does enough fine nutrient-rich material exist to create adequate foraging habitat?	Assess sediment samples throughout river reaches; compare to any samples or assessments taken prior to the 2011 flood. If possible, manipulate sediment composition on constructed sandbars.	ESH area, foraging habitat and nesting habitat area, # adults, # fledglings, forage quality (prey surveys).	
What ESH construction techniques are most cost-effective? What techniques can be used independent of flow magnitude? What construction strategies are most resilient?	Assess ESH developed using alternative construction methods (e.g. hydraulic dredging, mechanical dredging, placement of structures to trap sediments), including alternative containment/stabilization materials and designs.	Cost per unit area of standardized ESH; maximum annual production levels; erosion rates; range of implementable flows	

1 **Criteria for adjusting action:** *During implementation* of construction projects,
2 adjustments may be required to accommodate unexpected flow conditions. Contingency
3 plans should be included with sandbar design to accommodate changes to conditions
4 that would affect the outcome. *After implementation of projects:* Results from annual
5 habitat evaluations and experimental design of sandbar construction will help
6 determine best practices for sandbar location and design. These results, along with
7 observations and recommendations from the Bird Team or Technical Team, will be
8 captured in annual reporting and used to inform future project design. *Programmatic*
9 *adjustments:* If the rate of habitat construction needed to meet targets estimated by the
10 model is not producing the desired results, there may be bias in the model and/or flows
11 are consistently in more or less erosive ranges than expected. If effective adjustments to
12 the ESH model or hydrological predictions cannot be made, adjustments to the criteria
13 for determining how much to implement and when may be needed.

14 **Decision and collaboration level:** The Management Team allocates budget and
15 other resources to ESH construction, based upon recommendations of the Bird Team
16 and the balance of other MRRP needs. The Bird Team and implementation staff decides
17 the location, methodology, and design of construction activities based on best practices,
18 and the assigned PM manages contracts and monitoring. MRRIC is informed through
19 the WP. See Section 2.4.4.

20 **3.2.4.1.2 Flow management to avoid inundation of nests or chicks**

21 **Definition and function:** Once birds have initiated nesting, reservoir releases are
22 managed to minimize nest inundation or chick stranding by using a steady release/flow-
23 to-target release strategy. This approach recognizes that tributary inflows below Gavins
24 Point Dam typically decrease over the summer, potentially requiring increases in
25 releases from Gavins Point in order to meet downstream navigation targets. Such
26 increases can inundate nests at low elevations or inundate entire sandbars, leading to
27 mortality of pre-fledged chicks. By setting releases somewhat higher than necessary to
28 meet navigation targets at the beginning of the nesting season, later increases can be
29 avoided.

30 **Implementation criteria:** Steady releases are set in May based upon forecasts and
31 navigation expectations. Increases in flow above the elevation of known nests are
32 avoided to the extent possible. Short-term reductions in releases from Gavins Point
33 Dam may be used in cases of high discharge from downstream tributaries, to reduce
34 flood risk; if reductions are short enough that birds do not initiate nests at lower
35 elevations, releases can be returned to higher levels once downstream flood risks have
36 passed with low risk of take. Once eggs have hatched, releases can be increased
37 gradually as needed to meet navigation targets. The initial steady release is set in

1 anticipation of reduced tributary flows later in the summer to limit the necessary
2 increase. The range of flexibility for flows depends upon the sandbar elevation profiles
3 relative to target releases and resulting river stage. Releases may also be adjusted to
4 avoid having low-elevation sandbars just above the river stage that attract nesting birds
5 but are likely to be inundated.

6 **Constraints:** Releases from Gavins Point are also managed to meet flood control,
7 navigation, and water supply needs.

8 **Performance metrics:** Releases (cfs) during nesting season (including slope and
9 direction of changes), number of nests inundated, chick mortality, fledge ratios.

10 **Human considerations metrics:** Flow and stage are regularly monitored by the
11 MRBWMD at several locations on the Missouri River and serve as the basis for
12 monitoring of outcomes of flow management actions. No additional direct monitoring of
13 HC metrics is envisioned for this management action; however, additional studies may
14 be undertaken and additional metrics may be employed to address flow management
15 following the guidance and process outlined in Sections 2.3.3.2 and 5.5.5.

16 **Uncertainties, research, and active AM:** The effectiveness of flows to avoid
17 inundation of nests or chicks is assessed by observations during the nesting season, but
18 nest detection is not perfect. Loss of chicks is difficult to attribute to specific causes.
19 Flow management during the nesting season may also cause sub-lethal stress by
20 inundating foraging habitat or decreasing forage quality. Erosion rates may be affected
21 when flow is varied to meet downstream targets. Targeted research may be required to
22 determine lethal and sublethal effects of nesting season flow management and
23 effectiveness of steps to reduce those effects (Table 22). Inundation risk is difficult to
24 model beyond the current season given current capabilities. Information on sandbar
25 and nest elevation, together with model refinements, would improve predictions.

26 **Criteria for adjusting action:** *During implementation:* flows are adjusted in
27 response to downstream flood control targets and navigation, information from
28 productivity monitoring on nest elevations and at-risk nests, in balance with meeting
29 other authorized purposes. *After implementation:* Effects of flow management on
30 egg/chick mortality and outcomes of research may be used to adjust implementation
31 rules, with consideration of HC effects. This may require adjustments to the Master
32 Manual.

33 Table 22. Questions and study summaries for research and active AM regarding flow management to reduce
34 take.

Question	Study Summary	Metrics	Related studies
Management Uncertainty: To what extent can population protection actions positively contribute to the success of birds on the Missouri River?			
Associated Hypotheses: Steady or declining river flows during the nesting season increases survival from egg to chick and chick to fledgling by reducing the risk of nest inundation and chick stranding and by maintaining or increasing foraging habitat.			
What are the predicted effects of different magnitudes, durations, timing and frequencies of flows to reduce take on ESH, species, and HC metrics?	Modeling studies to assess a range of flow options; should be repeated following significant new information for ESH, population, and/or HC models as needed.	ESH acres (standard and available); fledgling production; population size; HC metrics (TBD)	
How do flow increases in July/August affect breeding success directly by flooding nests or by stranding chicks?	Additional focused monitoring of effects of flow increases during nesting season; if possible, explore range of flow increases when navigation requirements allow.	Nest success; egg loss; chick mortality.	Assessments of flow variability effects on nest success and chick mortality within normal operations (detection of chick mortality and ability to associate with cause is low with historical monitoring).
How do flow increases in July/August affect breeding success indirectly (starvation, etc.)?	Additional focused monitoring of effects of flow increases during nesting season; if possible, explore range of flow increases when navigation requirements allow.	Forage habitat; prey density and diversity; chick growth and weight.	Assessments of flow variability effects on forage habitat availability within normal operations currently or historically.
What are the effects of nesting season flow changes on erosion of ESH?	Additional focused monitoring of effects of flow increases during nesting season; if possible, explore range of flow increases when navigation requirements allow.	ESH acres; nesting and foraging habitat metrics; elevation profiles.	Assessments of flow variability effects on ESH area and nesting/foraging habitat within normal operations. Geomorphic assessments and monitoring of stage/area relationships.
What are the effects of flows to reduce take on HC metrics?	See Chapter 5		

1

2 **Decision and collaboration level:** These flows are routinely implemented by Water
 3 Management. Changes to operations needed to address unusual circumstances will be
 4 made by Water Management following guidelines in the Master Manual. Changes to
 5 how these flows are operated must be approved by MRBWMD at the Oversight level.

6 3.2.4.1.3 *Sandbar augmentation and modification*

7 **Definition and function:** Existing sandbars can be augmented or modified to
 8 increase ESH area and elevation and/or improve the quantity and quality of foraging
 9 habitat across a range of likely river stages. Modifications may include reshaping to
 10 increase edge/area ratios and reduce slopes or cutbanks. Augmentation or modification
 11 may be combined with vegetation removal.

1 **Implementation criteria:** Augmentation and modification should be used when
2 practical to extend the life of existing sandbars at reduced cost. Preference may be given
3 to sites with sufficient nesting area but low quantity or quality of foraging area.
4 Quantitative criteria and thresholds for ratio of nesting area to foraging area will be
5 determined in the course of AM. Sites with low nesting use relative to area, and sites
6 with lower fledge ratios than expected may be suitable candidates for modification.
7 Modification of existing sandbars may be contraindicated, however, if predation, human
8 activity or other persistent or recurring disturbances have been observed to affect
9 fledgling production or adult survival.

10 **Constraints:** Similar to sandbar construction, though modifications may require less
11 time, budget, and equipment than the creation of new sandbars. Implementation is only
12 meaningful when sandbars are of moderate age. It may not be practical to reshape
13 highly degraded sandbars, or as efficient for overall habitat creation as building new
14 sandbars.

15 **Performance metrics:** Acreage of standardized and available ESH on constructed
16 sandbars over time is used to track total area and sandbar longevity. Nesting site
17 selection and fledge ratios are used to assess the effectiveness of constructed habitat and
18 its contribution to overall population dynamics. Metrics for nesting vs. foraging habitat
19 and overall habitat quality will developed under the AM Plan.

20 **Human considerations metrics:** None identified. HC Impacts from augmentation
21 would likely be similar in type but of lesser magnitude than those that might be
22 identified during new construction. The AM Team and agency technical specialists
23 engaged in a screening exercise to identify concerns and potential monitoring and
24 assessment needs related to those concerns. The HC Team will, as its central charge,
25 make recommendations for monitoring needs and priorities as part of the WP
26 development process (see Section 2.4.4). The outcome of those deliberations will
27 determine which metrics (if any) may be employed.

28 **Uncertainties, research and active AM:** Little information currently exists on how
29 suitable modified habitat would be relative to newly created sandbars. Before-after-
30 control-impact experiments with sandbars of similar size and shape to track evolution of
31 the sandbars and bird use and productivity would provide evidence for effectiveness.
32 Comparisons of bird use of and productivity on modified sandbars compared to
33 constructed or flow-created sandbars, using multivariate analysis to control for sandbar
34 size, age, and other factors, should be used to test the effectiveness of modified sandbars
35 and/or particular designs of modified sandbars . Sandbar modification studies are listed
36 in Table 23.

1 Table 23. Questions and study summaries for sandbar augmentation and, modification research and active
 2 AM.

Question	Study Summary	Metrics	Related studies
Management Uncertainty: To what extent can maintaining existing habitat contribute to population objectives compared to creating new habitat?			
Associated Hypotheses: Augmentation/reshaping of existing sandbars increases nesting/brood-rearing and foraging area, which increases survival of eggs to chicks and chicks to fledglings by reducing predation and increasing food availability.			
Augmentation/reshaping of existing sandbars increases nesting/brood-rearing and foraging area relative to the condition and availability of habitat at other breeding areas, thus increasing the number of adults through net immigration from other areas.			
How does sandbar modification influence use of sandbars by nesting plovers and fledgling productivity? Under what conditions should sandbars be modified?	Modify selected sandbars and compare with unmodified sandbars of similar characteristics; use before-after-control-impact study design.	ESH acres; nesting and foraging habitat; elevation profiles; bird use and fledgling production.	Once general effects of modification have been studied, effects in conjunction with vegetation modification should be evaluated.
What ratio of nesting to foraging habitat is necessary to support optimal productivity?	Modify selected sandbars and compare with unmodified sandbars of similar characteristics; use before-after-control-impact study design.	ESH area, foraging habitat and nesting habitat area, # adults, # fledglings.	Assess historical sandbar ratios of nesting to foraging habitat and other metrics and site selection/fledgling production.
What designs for modification of sandbars are effective?	Compare modification techniques on otherwise similar sandbars; use before-after-control-impact design.	ESH area, foraging habitat and nesting habitat area, # adults, # fledglings.	Once general effects of modification design have been studied, effects in conjunction with vegetation modification should be evaluated.
Does modified ESH have higher predation risks than new construction?	Measure predation rates on modified sandbars and similar new sandbars.	Predation observations; fledge ratios	May overlap with studies for vegetation modification

3

4 **Criteria for adjusting action:** *After implementation:* adjustments may be needed if
 5 modifications do not last. If performance metrics do not respond as expected, then
 6 either modification methods were not well-designed or sufficient in magnitude, location
 7 is unsuitable (e.g. especially vulnerable to erosion due to proximity to thalweg) or
 8 unusual flows adversely affected the habitat form. If modified sandbars are less used or
 9 less productive than newly constructed bars or predation increases, and problems
 10 cannot be corrected, the overall effectiveness of modification as a tool for habitat
 11 management should be reevaluated. Cost-effectiveness should be considered with the
 12 aid of modeling to determine value of continuing modifications (e.g. do large amounts of
 13 moderate quality modified habitat produce as many birds as small amounts of high
 14 quality newly-constructed habitat for the same or lesser cost.)

1 **Decision and collaboration level:** The Management Team decides on the budget
2 available for habitat modification as well as construction, as informed by the Technical
3 and Bird Teams. The Bird Team and implementation staff decide on location,
4 methodology, design and contracting based upon identified best practices. MRRIC is
5 informed through the work plan.

6 3.2.4.1.4 *Vegetation management*

7 **Definition and function:** Vegetation management includes any non-flow means of
8 reducing or preventing vegetation growth on sandbars to improve ESH area and quality
9 and reduce predation. Spraying post-emergent herbicides in the fall, aerially or via land-
10 based equipment, is thought to be an effective means of controlling vegetation. Mowing
11 may be used on established vegetation, but removal or burning of biomass will generally
12 be required if treated habitat is to attract nesting birds.

13 **Implementation criteria:** Vegetation management should be implemented whenever
14 possible on early vegetation growth, before woody vegetation such as cottonwoods and
15 willows become established. Larger areas may be treated more effectively and quickly
16 through aerial applications.

17 **Constraints:** The extent of sandbar area that can be gained through vegetation control
18 is limited to the amount of vegetated area in early successional states. Vegetation
19 control may not be implementable if flows are too high during the fall, though higher
20 flows of sufficient duration may also remove vegetation or limit growth. Limits on the
21 use of herbicides might restrict application in certain locations.

22 **Performance metrics:** Area of standardized ESH and reduction in vegetated area;
23 bird nesting use and fledging success on vegetation-managed habitat.

24 **Human considerations metrics:** MRRIC members have previously expressed
25 concerns about water quality when spraying is implemented. The AM Team and agency
26 technical specialists engaged in a screening exercise to identify concerns and potential
27 monitoring and assessment needs related to those concerns. The HC Team will, as its
28 central charge, make recommendations for monitoring needs and priorities as part of
29 the Work Plan development process (see Section 2.4.4). The outcome of those
30 deliberations will determine which metrics (if any) may be employed relative to
31 vegetation management.

32 **Uncertainties, research, and active AM::** An initial before-after-control-impact
33 study suggests that spraying is effective at reducing the establishment of emergent
34 vegetation, but additional evidence of vegetation dynamics on treated sandbars and bird

1 use and productivity is necessary. Experimental spraying, mowing, and burning of
 2 *Phragmites* on sandbars in the Lewis and Clark Lake delta is underway to determine if
 3 effective removal is possible. Comparisons of bird use of and productivity on vegetation-
 4 managed sandbars compared to constructed or flow-created sandbars, using
 5 multivariate analysis to control for sandbar size, age, and other factors, should be used
 6 to test the effectiveness of vegetation management and/or particular methodologies.

7 **Criteria for adjusting action:** *After implementation:* if vegetation-managed
 8 sandbars are not used for nesting at levels comparable to newly created sandbars,
 9 and/or fledgling production is not comparable, use of methodologies should be
 10 reevaluated. The AM process will identify thresholds that should be exceeded for
 11 continued application. (E.g. if bird use of a treated site is less than <50%> of
 12 comparable unvegetated sites or if fledgling production is less than <75%> of
 13 comparable sites or target fledge ratios, then the methodology or choice of sites should
 14 be reevaluated.) Cost-effectiveness should be considered with the aid of modeling to
 15 determine value of continuing management (e.g. do large amounts of moderate quality
 16 vegetation-managed habitat produce as many birds as small amounts of high quality
 17 newly-constructed habitat for the same or lesser cost.)

18 Table 24. Questions and study summaries for vegetation management research and active AM.

Question	Study Summary	Metrics	Related studies
Management Uncertainty: To what extent can maintaining existing habitat contribute to population objectives compared to creating new habitat?			
Associated Hypotheses: Vegetation removal increases survival of eggs to chicks and chicks to fledglings by reducing predation (by increasing nesting/brood-rearing area and by removing cover for predators). Vegetation removal increases nesting/brood-rearing and foraging area, which increases survival of chicks to fledglings by increasing food availability. Vegetation removal increases nesting/brood-rearing and foraging area relative to the condition and availability of habitat at other breeding areas, thus increasing the number of adults through net immigration from other areas.			
Does spraying vegetation reduce the amount of vegetation on sandbars to provide for suitable nesting habitat?	Spraying of test sites with before-after-control-impact design (some studies already conducted/underway). Age, successional stage, and species of vegetation must be taken into account.	Transects and imagery assessments of vegetation before and after treatment and relative to control sites; bird use and productivity at treated vs. control sites; predation rates.	Once understanding of effects of vegetation modification, may experiment in conjunction with sandbar augmentation.
Can <i>Phragmites</i> and other wetland vegetation be successfully removed from sandbars in the Lewis and Clark Lake delta?	Spraying, mowing, and burning of wetland vegetation on Lewis and Clark Lake sandbars (study underway). Age, successional stage, and species of vegetation must be taken into account.	Transects and imagery assessments of vegetation before and after treatment and relative to control sites; bird use and productivity at treated vs. control sites; predation rates.	

Question	Study Summary	Metrics	Related studies
What are the successional dynamics/revegetation rates of sandbars following flow creation, mechanical creation, or vegetation management action? Are they different between habitats created by different methods? How have these activities influenced the seed source for revegetation?	Treatment of test sites on habitat previously created, modified, and/or treated through different means.	Transects and imagery assessments of vegetation following the management action annually. Take core samples to measure seed bank.	
What are the direct or indirect effects on invertebrate prey base for piping plovers from vegetation control, either through the loss of vegetation or effects of herbicides on prey (if any). How does the effect on prey base affect productivity?	Spraying of test sites with before-after-control-impact design.	Measure invert abundance along transects and organic nutrient content, Transects and imagery assessments of vegetation before and after treatment and relative to control sites; bird use and productivity at treated vs. control sites. Measure for residual herbicide.	
How does vegetation (species, density, distribution, etc.) affect erosion rates for ESH and what are the tradeoffs between erosion and productivity?	Assess bars with different vegetation conditions using a BACI study design.	Erosion rate and productivity as a function of vegetation type, density, distribution, location on the bar, and age.	Constructed bars with vegetation used to assess construction strategy or design.
Does vegetation-controlled ESH have higher predation risks than new construction?	Measure predation rates on modified sandbars and similar new sandbars.	Predation observations; fledge ratios	May overlap with sandbar modification studies.

1

2 **Decision and collaboration level:** The Management Team decides on the budget
 3 available for vegetation management as well as construction, as informed by the
 4 Technical and Bird Teams. The Bird Team and implementation staff decide on location,
 5 methodology, design and contracting based upon identified best practices. MRRIC is
 6 informed through the work plan

7 3.2.4.1.5 *Predation management*

8 **Definition and function:** Predation management includes nest caging for plovers
 9 and predator removal to reduce mortality of eggs, nests and adults and increase fledge
 10 ratios. Nest caging is not suitable for terns.

11 **Implementation criteria:** Nest caging should be initiated when the density of both
 12 plovers and terns exceeds a threshold (TBD during AM process) or when predation
 13 effects begin to be observed. The presence and extent of vegetation, connectivity to
 14 shore, proximity to trees, and other factors that increase predation risk should be
 15 considered when determining the need for predation management.

1 **Constraints:** Effectiveness is primarily linked to the ability to detect nests (for caging)
 2 and detect and remove predators. Predation rates are typically lower and management
 3 less necessary when bird population densities are low (habitat is relatively abundant);
 4 thus benefits gained from management are primarily observed when densities are high.
 5 Caging of plover nests can result in increases in mortality for adult plovers.

6 **Performance metrics:** Predation observations (it may not be possible to estimate
 7 rates); number of predators removed; nesting success and fledgling production on
 8 sandbars with predation management.

9 **Human considerations metrics:** None identified. Relevant metrics that emerge
 10 from the MRRIC engagement will be added to the next version of the AM Plan.

11 **Uncertainties and opportunities to improve management decisions:** A
 12 relationship between population density and predation has not been quantified, nor
 13 have thresholds been identified due to limited data. Causes of nest loss and chick
 14 mortality are not always known, and mortality may be undetected, especially for new
 15 nests and chicks near fledging. Some data exists for effectiveness of nest caging and
 16 predator control and effects of cages on adult mortality, but most data has been
 17 collected on other habitat types (e.g. alkali wetlands, ocean beaches) rather than the MR
 18 and high uncertainty remains about effectiveness. Enhanced monitoring or research to
 19 detect predation, quantify density-predation relationships, and identify other risk
 20 factors at the local or landscape scale as well as experimental design of management
 21 practices would aid in measuring effectiveness and predicting population impacts. The
 22 use of cameras to detect predators has been studied and may provide useful data in lieu
 23 of more extensive monitoring.

24 Table 25. Questions and study summaries for predation control research and active AM.

Question	Study Summary	Metrics	Related studies
Management Uncertainty: To what extent can population protection actions positively contribute to the success of birds on the Missouri River?			
Associated Hypotheses: Predation removal increases survival of eggs to chicks and chicks to fledglings.			
At what acreage and nest density does predation have significant population effects?	Increase monitoring at study sites to improve detection of predation (may be able to use cameras).	Presence/absence of predators and predator evidence. Percent of nests lost to predation through the field season relative to ESH area and nesting density.	

Question	Study Summary	Metrics	Related studies
What are the predominant predators? Do they vary spatially? Does predation decrease as the field season progresses (as other species initiate nests or predators tend to their own young)? Does this decline then allow for adequate productivity rates to support a growing population? Does it vary predictably year to year?	Evaluate presence/absence of predators and predator evidence and the rates of predation on nests and chicks throughout the field season. Identify predominant predators. Assess predator type spatially along the river corridor.	Presence/absence of predators and predator evidence. Percent of nests lost to predation through the field season and year over year. Shifts in predator composition with space and time.	
Can we successfully implement predation management actions? Under what conditions (if any) can predation management be successful?	Implement predation control program measured against similar habitat areas with no predation control	Successful nests, # of fledglings compared to similar non-treated areas	If predation management is successful - determine the factors that created success

1

2 **Criteria for adjusting action:** *During implementation:* observations of high density
 3 nesting and/or predation trigger initiation of or increases in management, if resources
 4 allow, during the nesting season. *After implementation:* Experimental design of
 5 management practices and/or more intensive monitoring should be used to assess
 6 effectiveness of predation management and identify adjustments.

7 **Decision and collaboration level:** Implementation staff decide on amount and
 8 locations as informed by the Technical Team, Bird Team, and ongoing monitoring
 9 during the season.

10 3.2.4.1.6 *Human restrictions measures*

11 **Definition and function:** Human restrictions measures include signs and symbolic
 12 fences, as well as education, to restrict people from entering nesting areas. These
 13 measures are intended to reduce stress on birds and decrease mortality of eggs, chicks,
 14 and adult from people, vehicles, and pets.

15 **Implementation criteria:** Generally implemented for all sandbars where nesting is
 16 observed. Not always used on isolated areas of reservoir shoreline with low human
 17 activity.

18 **Constraints:** Human restriction measures require low effort and resources to
 19 implement, but are difficult to enforce.

- 1 **Performance metrics:** Evidence of nest/chick loss attributable to human activity
 2 (detection rates may be low); evidence of human presence on sandbars; nesting and
 3 brood-rearing success on sandbars with human restriction measures in place.
- 4 **Human considerations metrics:** Human restriction measures limit access to
 5 sandbars for recreation during the nesting season. Relevant metrics that emerge from
 6 MRRIC engagement will be added to the next version of the AM Plan.
- 7 **Uncertainties, research, and active AM:** As with predation, the effects of human
 8 activity are not well known as not all nests are detected and not all cause of egg/chick
 9 loss can be accurately identified. Adverse, especially sublethal, effects of human
 10 disturbance (stress, impacts on foraging) are difficult to quantify. Thus the contribution
 11 of the action to population dynamics is difficult to estimate and predict.
- 12 **Criteria for adjusting action:** *During implementation:* observations of problematic
 13 human activity or nesting in known sites of high activity trigger increased management
 14 during the nesting season. *After implementation:* Experimental design of management
 15 practices and/or more intensive monitoring should be used to assess effectiveness of
 16 human restrictions measures and adjust as necessary.
- 17 **Decision and collaboration level:** Restriction measures are implemented by
 18 default; the Bird Team and implementation staff make any necessary decisions on
 19 locations and methods.

20 Table 26. Questions and study summaries for human restrictions measures research and active AM.

Question	Study Summary	Metrics	Related studies
Management Uncertainty To what extent can population protection actions positively contribute to the success of birds on the Missouri River?			
Associated Hypotheses Human restriction measures reduce human activity on nesting and foraging habitat, increasing survival both by decreasing direct mortality and indirect effects on survival caused by stress.			
What level of human activity occurs on sandbars with and without signs? How often do lethal impacts occur?	Observation of control and treated sites, particularly during weekends/holidays, to observe effectiveness of signing or other restriction measures.	Evidence of human activity. Number/percent of nests lost to human impacts through the field season relative to sandbar location and management activities.	Monitoring/cameras to detect predation may also increase detection of human activity.

Question	Study Summary	Metrics	Related studies
Are there alternative measures of reducing human activity in nesting areas that are more effective?	Observation of sites with alternative restriction measures, particularly during weekends/holidays, to observe effectiveness of signing or other restriction measures.	Evidence of human activity. Number/percent of nests lost to human impacts through the field season relative to sandbar location and management activities.	

1

2 3.2.4.2 *Actions for Research and Pilot-Scale Implementation (Evaluated in the MRRMP-EIS)*

3 Actions described in this section were evaluated in the EA and as part of the alternatives
 4 in the DEIS and found to have beneficial effects for plovers, but were not included in the
 5 preferred alternative. If it is determined after the ROD that there is need for these
 6 management actions, steps will be taken prior to implementation that may include
 7 additional NEPA processes if the EIS analyses no longer suffice. Additional decision
 8 documents and changes to the Master Manual may also be required before full
 9 implementation. (Section 1.1.6).

10 Uncertainty remains about the effectiveness of actions in this section. The AM process
 11 may take advantage of events occurring within typical system operations (e.g. high or
 12 low releases necessary according to the current Master Manual) to conduct research
 13 about the potential effects of flow modifications. The research and pilot-scale
 14 implementation (e.g. flow tests) described in this section are roughly analogous to Level
 15 1 and Level 2 actions for pallid sturgeon (Section 4.2.1.1). However, unlike for sturgeon,
 16 timelines have not been established for implementation of these studies or actions, as
 17 the set of actions in the preferred alternative have been determined during the EIS
 18 process as able to meet piping plover targets. Pilot projects or flow tests may be
 19 implemented using site-specific NEPA processes or within the scope of water
 20 management rules following the ROD and any ensuing Master Manual revisions.

21 Changes made to the set of bird actions included in the selected alternative as identified
 22 in the ROD could result in changes to this section of the Plan.

23 3.2.4.2.1 *Habitat-forming flow release*

24 **Definition and function:** Releases exceeding 30kcfs from Garrison Dam, 40kcfs
 25 from Ft. Randall Dam, and 50kcfs from Gavins Point Dam are expected to deposit more
 26 sand than is eroded, increasing the amount of standardized ESH. The amount of ESH
 27 created depends on the magnitude and duration of the flow release and the area of
 28 sandbar present prior to the release (ambient ESH). These flows occur occasionally
 29 when high runoff requires above-normal releases, but have not been implemented with

1 a goal of creating ESH. A deliberate release of flows in the spring (March through May)
2 or fall (October through December) to create ESH is expected to be an effective
3 management action for plovers and terns.

4 **Implementation criteria:** *If selected as a management action for full*
5 *implementation:* Habitat-forming flow releases under evaluation in the DEIS are the
6 following:

- 7 • A spring release initiated on April 1st consisting of a 60 kcfs release from Gavins
8 Point and Fort Randall dams and 42.5 kcfs from Garrison dam for a 5.5 week
9 duration. System storage must be greater than 42 MAF.
- 10 • A fall release is initiated on October 17th consisting of a 60 kcfs release from Gavins
11 Point and Fort Randall dams and 42.5 kcfs from Garrison dam for a 5.5 week
12 duration. The service level must be greater than 35 kcfs.

13 Implementation may include releases of lesser magnitude or duration than as specified,
14 but will not exceed these magnitudes or durations without a formal process to change
15 the flow definitions (See Attachment 6).

16 *If implemented as a flow test:* Criteria for any potential implementation as a test flow
17 (including requirements prior to testing and conditions under which it would not be
18 tested) will be determined following the review period for the DEIS.

19 **Constraints:** *(If selected as a management action for full implementation)* Habitat-
20 forming flows will not be used more frequently than once every 4 years, nor within 4
21 years of any naturally-occurring flow that created 250 acres or more of standardized
22 ESH. They will not be used when ambient ESH levels exceed 25% of target acreage in
23 the reach of concern, or when system storage is less than 42MAF for a spring release or
24 the service level is less than 35 kcfs for a fall release. If combined releases plus tributary
25 flows exceed flood thresholds (71kcfs at Omaha, 82kcfs at Nebraska City, or 126kcfs at
26 Kansas City), releases are decreased by 5 kcfs increments until downstream flow criteria
27 are met or the release falls below 45 kcfs, at which point it is terminated.

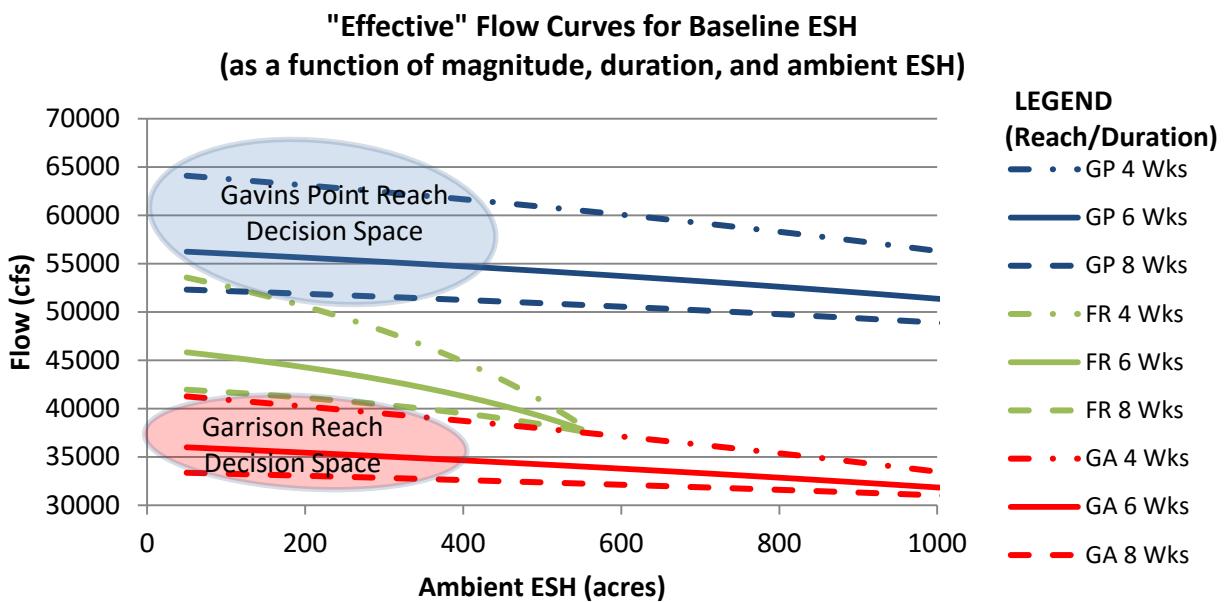

28 The effectiveness of habitat-forming flows is a function of ambient ESH acreage; when
29 acreages are high, flow releases may erode more sandbar area than is created.

30 **Performance metrics:** Standardized ESH acreage before and after the flow release
31 measures the effectiveness of the releases. Sandbar elevation profiles should be surveyed
32 to measure effectiveness of flow releases for creating habitat available across a range of
33 typical nesting season flows. Nesting bird densities and fledge ratios are used to assess
34 the quality of flow-created habitat and its contribution to overall population dynamics.

1 Metrics for nesting and foraging habitat and overall habitat quality have not been used
2 historically but will be developed under the AM Plan. Flow releases may result in more
3 habitat on reservoirs the following season; reservoir habitat metrics and bird
4 productivity should also be assessed as an outcome of habitat-forming flows.

5 **Human considerations metrics:** For any implemented flow action, the MRBWMD
6 monitors flow throughout the basin by tracking observed stage at key locations, and
7 calculates flow and stage at remaining locations using calibrated and validated models
8 and rating curves. Additional HC-specific metrics could be identified to assess outcomes
9 of action implementation. Section 5.5.5 outlines the process by which the AM Team and
10 agency technical staff have assessed uncertainties and potential monitoring and
11 assessment opportunities. Pending the recommendations of the HC Team and decisions
12 regarding the Work Plan scope (see Sections 2.3.3.2 and 2.4.4, respectively), both pre-
13 and post-monitoring assessments of identified HC metrics may be needed to assure the
14 flows are not impacting HC interests.

15 **Uncertainties, research, and active AM:** The amount of habitat created by any
16 specific combination of flow magnitude and duration is variable and uncertain and
17 depends upon the initial distribution and supply of sediment, among other factors. The
18 longevity of created ESH is also uncertain, as it is dependent upon the subsequent flows,
19 which are unknown but can be statistically represented. Habitat quality and long-term
20 availability will depend upon the elevation of sandbars created by the flow; current
21 predictive capacities are limited in this respect. Each implementation, therefore, will
22 provide valuable information for model development and/or validation, which will help
23 refine future implementation decisions.

1

2 Figure 45. Anticipated range of "effective" combinations of flow and duration that meet standardized acreage
3 targets given initial ambient ESH, with presumed "decision space" shown for Gavins Point and Garrison
4 reaches.

5 Learning can be enhanced by a) implementing flows when possible given the necessary
6 conditions exist, b) monitoring sandbar evolution during "natural" flow events, and c)
7 implementing a range of flow magnitudes, duration, and timing, even if conditions allow
8 for a release that could be more effective but has already been implemented.
9 Additionally, monitoring of key HC metrics will validate/improve existing relations
10 between habitat creation flows and impacts to interior drainage and flood risk concerns.
11 Further discussion can be found in Section 3.5.7.

12 Table 27. Questions and study summaries for habitat-creating flow research and active AM.

Question	Study Summary	Metrics	Related studies
Management Uncertainty			
Are there effective and implementable ways of using flow management to improve habitat availability and quality? What are the effects of habitat creation actions on Human Considerations?			
Associated Hypotheses			
Habitat-creating flows of sufficient magnitude and duration increase the area of nesting/brood rearing habitat and foraging habitat on the river by increasing deposition, assuming sediment is available, thereby increasing fledgling productivity.			
What are the predicted effects of different magnitudes, durations, timing and frequencies of habitat-forming flows on ESH, species, and HC metrics?	Modeling studies to assess a range of flow options; should be repeated following significant new information for ESH, population, and/or HC models as needed.	ESH acres; fledgling production; population size; HC metrics (TBD)	

Question	Study Summary	Metrics	Related studies
What is the relationship between proposed habitat-creating flows and ESH area created?	Implement flows when conditions permit; explore effects of different initial conditions and flow parameters; track evolution of habitat.	ESH acres; nesting and foraging habitat; elevation profiles; bird use and fledgling production.	Geomorphic assessments of flow variability effects on ESH within normal operations.
What are the effects of habitat forming flow implementation on HC metrics?	See Chapter 5		
How will changes to sediment supply and channel morphology (including aggradation/degradation) alter the effects of flow releases on ESH deposition?	Conduct a numerical modeling study to assess the effects of decreasing sediment supply, coarsening of sediment gradation and lowering of bed profile on ESH/flow relationships. Validate model study results using trends from monitoring over time.	“Effectiveness” of flows (magnitude and duration) in creating ESH (acres) as measured by departure from current response curves.	Geomorphic investigations of sandbars in the Garrison and/or Gavins reaches.

1

2 **Criteria for adjusting actions:** *During implementation*, if combined releases plus
 3 tributary flows exceed flood thresholds (71kcfs at Omaha, 82kcfs at Nebraska City, or
 4 126kcfs at Kansas City), releases are decreased by 5 kcfs increments until downstream
 5 flow criteria are met or the release falls below 45 kcfs, at which point it is terminated.
 6 *After implementation*, monitored impacts will be compared with the level of acceptable
 7 impact determined in coordination with MRRIC. If results fall outside the acceptable
 8 range, adjustment to the action specification (i.e. the “decision space”) may be made to
 9 avoid or reduce risks in the future. Similar adjustments might be made if the observed
 10 benefits deviate significantly from projected values. However, given the complex nature
 11 of the system, any adjustments should be made with the best possible understanding of
 12 why the deviation occurred, the expected range of natural variation and the likelihood of
 13 re-occurrence. E.g. an extreme hydrological event during implementation may skew
 14 many outcomes and not give a realistic assessment of action effectiveness and impacts.
 15 The tolerance for unusual outcomes and the ability to repeat actions despite them will
 16 be different for actions with unexpectedly high HC impacts versus those with
 17 unexpectedly low ESH creation, as repeating instances of the latter carries lower risk.

18 **Decision and collaboration level:** (See Section 0; Workflows 3-6). For flows within
 19 the decision space of the ROD, the Bird Team can recommend a flow action as a
 20 management option. The Management Team will balance this option with other
 21 management needs and expected positive and negative effects. Should the Management
 22 Team recommend a flow, implementation must be approved by MRBWMD, who
 23 informs MRRIC of intent, monitors for impacts and reviews after-action assessment
 24 with MRRIC. If the Management Team decides the decision space for flows needs to
 25 change based on evaluations from the Technical Team or Bird Team recommendations,

1 Oversight must approve the proposed changes after consultation with the MRBWMD
2 and MRRIC.

3 *3.2.4.2.2 Lowered nesting season flow*

4 **Definition and function:** The availability of ESH during the nesting season (~May
5 15-August 15) depends on flows. Lowered flows expose more ESH and may also reduce
6 erosion of ESH during the year, depending upon how water held back is released.
7 Lowered nesting season flows are limited to Fort Randall and Gavins Point dams. If
8 water is held back, lowered nesting season flows reduce nesting habitat availability in
9 the reservoirs relative to if flows had not been reduced.

10 **Implementation criteria:** *As implemented according to the 2006 Master Manual:*
11 Opportunity to provide low summer flows exists under the current Master Manual,
12 dependent primarily on system storage level and the status and location of commercial
13 navigation on the river. Plate VI – 1 in the Master Manual shows the service level related
14 to system water supply. If the water supply is such that water must be evacuated from
15 the system low summer flows would not be likely during the nesting season. However
16 during droughts when water conservation is a priority and service level is less than full
17 service low summer flows are likely.

18 Section 7-13.1.1 of the Master Manual describes the manner in which day-to-day
19 regulation of the system to support navigation will be accomplished. Anticipated traffic
20 or the absence of traffic at the control points will have a bearing on the selection of the
21 control point for providing the service level. After selection of the control point, System
22 releases are adjusted so that in combination with anticipated tributary flows they will
23 meet the target flow at the control point. This affords an opportunity to provide low
24 summer flows if navigation traffic is below Omaha so the control point is Nebraska City
25 or Kansas City and enough tributary flow is present to allow for low summer flows.¹

26 *If implemented specifically for providing ESH:* If available ESH has been below percent
27 exceedance targets over the period of evaluation, the ability of reduced flows to increase
28 the likelihood of meeting targets should be evaluated. Similarly, if standardized ESH
29 area is below the median target and the ability to create new habitat through flows or
30 construction in the near future is projected to be limited (e.g. insufficient system storage

¹ The years 2007 and 2008 provide an example of water conservation and high downstream flows coupled with missing navigation targets in the Sioux City and Omaha reaches produced very low releases from Gavins Point during the bird nesting season. Releases ranged from 10.5 kcfs to 21.5 kcfs in 2007 and 13.1 kcfs to 22.8 kcfs in 2008. For comparison purposes the average release from Gavins Point since the system filled in 1967 ranges from 28.5 kcfs to 36.6 kcfs during the bird nesting season.

1 or budget), lowered summer flows should be given additional consideration as they can
2 increase the longevity of existing habitat by reducing erosion and/or allow for habitat-
3 creating flows in the fall. If the standardized ESH area is very low, benefits of lowered
4 nesting flows are less and may not be worth impacts to reservoir habitat and/or HC.

5 Bird population densities should be greater than <TBD> for lowered nesting season
6 flows to be beneficial; at lower densities additional habitat is not needed. As reduced
7 flows in the southern reaches affect habitat in the northern reservoirs (Sakakawea and
8 Oahe), consideration should also be given to habitat and population trends in the
9 reservoirs, with lower flows a higher priority when the southern region is less likely to
10 meet habitat and/or population targets than the northern region. Model evaluation of
11 habitat availability and expected population density should be used to assess benefits
12 prior to implementing flows. [Note: Implementation criteria will be quantified following
13 additional hydrological modeling and finalization of the bird EA report.]

14 **Constraints:** The ability to lower nesting season releases from Gavins Point Dam
15 depends on downstream flows to meet targets, inflows downstream of Gavins Point
16 Dam and basin hydrologic conditions. Lowered nesting season releases from Garrison
17 Dam have not yet been investigated; additional constraints would apply should lowered
18 nesting season releases be applied to the Missouri River between Lakes Sakakawea and
19 Oahe.

20 **Performance metrics:** Standardized and available ESH during lowered releases
21 measures the effectiveness of lowered flows increasing the availability of nesting and
22 foraging habitat. Standardized ESH measurements in the year following the flow are
23 used to assess any net effects on erosion. Reservoir habitat metrics must also be
24 evaluated to measure the tradeoff between downstream ESH and reservoir shoreline
25 habitat. Fledgling production in both river and reservoir segments should be evaluated
26 to determine net effects of lowered flows.

27 **Human considerations metrics:** For any implemented flow action, the MRBWMD
28 monitors flow throughout the basin by tracking observed stage at key locations, and
29 calculates flow and stage at remaining locations using calibrated and validated models
30 and rating curves. Additional HC-specific metrics could be identified to assess outcomes
31 of action implementation. Section 5.5.5 outlines the process by which the AM Team and
32 agency technical staff have assessed uncertainties and potential monitoring and
33 assessment opportunities. Pending the recommendations of the HC Team and decisions
34 regarding the Work Plan scope (see Sections 2.3.3.2 and 2.4.4, respectively), both pre-
35 and post-monitoring assessments of identified HC metrics may be needed to assure the
36 flows are not impacting HC interests.

1 **Uncertainties, research, and active AM:** Uncertainty remains in the estimation of
 2 the relationship between flow/stage and sandbar habitat availability; this relationship
 3 varies with time and location and thus requires periodic re-evaluation, particularly
 4 following high flow events. Imagery acquisition, LiDAR and/or elevation surveys during
 5 lowered flows provide additional information about flow/area relationships and
 6 sediment dynamics at lower flows. Implementation of a range of reduced flows under
 7 different conditions would accelerate learning.

8 Table 28. Questions and study summaries for lowered nesting-season flow research and active AM.

Question	Study Summary	Metrics	Related studies
Management Uncertainty To what extent can improving the availability of existing habitat through flows contribute to -population objectives compared to creating new habitat?			
Associated Hypotheses Reduced summer flows increase the area of suitable nesting and brood rearing habitat and foraging habitat on the river, thereby increasing fledgling productivity.			
What are the predicted effects of different magnitudes, durations, timing and frequencies of lowered nesting-season flows on ESH, species, and HC metrics?	Modeling studies to assess a range of flow options; should be repeated following significant new information for ESH, population, and/or HC models as needed.	ESH acres (standard and available); fledgling production; population size; HC metrics (TBD)	
What is the relationship between lowered nesting season flows, nesting and foraging habitat, and fledgling production?	Implement varied flows when conditions permit; explore effects of different initial conditions and flow magnitude and duration.	ESH acres; nesting and foraging habitat; bird use and fledgling production.	Assessments of flow variability effects on ESH area and fledgling production within normal operations. Geomorphic assessments and monitoring of stage/area relationships.
What are the effects of lowered nesting season flows on HC metrics?	TBD: See Chapter 5		
How will changes to channel morphology (including aggradation and degradation) alter the effects of nesting season flows on habitat availability?	Conduct a numerical modeling study to assess the effects of decreasing sediment supply, coarsening of sediment gradation and lowering of bed profile on ESH elevations. Validate model study results using trends from monitoring over time.	Exposure of ESH (acres) at low discharge values and trends therein.	Geomorphic investigations of sandbars in the Garrison and/or Gavins reaches.

9

10 **Criteria for adjusting action:** Actions are implemented within a range of acceptable
 11 risks (of undesirably high impacts, undesirably low benefits, or both). If results fall
 12 outside the acceptable range, adjustment to the action specification (i.e. the “decision
 13 space”) may be made to avoid or reduce risks in the future. Similar adjustments might

1 be made if the observed benefits deviate significantly from projected values. However,
2 given the complex nature of the system, any adjustments should be made with the best
3 possible understanding of *why* the deviation occurred and the likelihood of re-
4 occurrence. E.g. an extreme hydrological event during implementation may skew many
5 outcomes and not give a realistic assessment of action effectiveness and impacts. The
6 tolerance for unusual outcomes and the ability to repeat actions despite them will be
7 different for actions with unexpectedly high HC impacts versus those with unexpectedly
8 low ESH creation, as repeating instances of the latter carries lower risk.

9 Currently, lowered flows in summer can be implemented when other requirements such
10 as navigation do not need to be met or when runoff is very low as described above. These
11 modifications are constrained by other authorized purposes and not focused on optimal
12 effects for bird nesting. In the case that lowered summer flows are determined to be
13 both effective and necessary for more regular implementation or implementation
14 triggered by ESH or bird population conditions, a supplemental EIS would be prepared
15 if not already covered by the MRRMP/EIS, and the process for changing the Master
16 Manual technical criteria would be exercised, if required (see Attachment 6 of Appendix
17 A).

18 **Decision and collaboration level:** For flows within the decision space, the
19 Management Team recommendation to implement must be approved by MRBWMD,
20 who informs MRRIC of intent, monitors for impacts and reviews the after-action
21 assessment with MRRIC. If the Management Team decides the decision space for flows
22 needs to change based on recommendations from the Technical Team, Oversight must
23 approve the proposed changes after consultation with the MRBWMD and MRRIC.

24 3.2.4.3 *Actions for Research and Pilot-Scale Implementation (Not Evaluated in the MRRMP-*
25 *EIS)*

26 Actions described in this section were identified in the EA or the PrOACT process as
27 potential management actions but were not evaluated as part of the alternatives in the
28 DEIS. Additional evidence for the effectiveness of these actions from research and/or
29 field testing is required to determine whether full-scale implementation should be
30 considered. The research activities and pilot-scale implementation described in this
31 section are roughly analogous to Level 1 and Level 2 actions for pallid sturgeon (Section
32 4.2.1.1). However, unlike for sturgeon, timelines have not been established for
33 implementation of these studies or actions, as the set of actions in the preferred
34 alternative have been determined during the EIS process as able to meet piping plover
35 targets.

1 Pilot projects or tests may be implemented using site-specific NEPA processes or within
2 the scope of water management rules following the ROD. If evidence for action
3 effectiveness supports broader implementation, supplemental programmatic NEPA
4 coverage will likely be required prior to full-scale implementation. New actions that may
5 be added during the course of the AM process would be added to this section.

6 3.2.4.3.1 *Non-sandbar habitat creation or modification*

7 **Definition and function:** The USFWS has determined that created habitat other than
8 sandbars must be hydrologically connected, i.e. it regularly comes into contact with the
9 mainstem river or reservoirs, in order to contribute to bird objectives for the MRRP.
10 Projects must fall within the USACE' management authority. Habitat types that have
11 been proposed include:

- 12 • Habitat creation or modification on reservoir shorelines: habitat that is created,
13 modified, or maintained to improve physical characteristics (slope or substrate),
14 reduce or remove vegetation growth and reduce non-avian predation (e.g. through
15 fencing); may be employed at different elevations to provide habitat when reservoirs
16 are filling over multiple years.
- 17 • Created islands in reservoirs: habitat that is created in reservoirs but not attached to
18 the shoreline, to reduce predation and other disturbances. In some locations such as
19 small side bays water control measures may be considered to provide habitat less
20 subject to inundation during the nesting season.
- 21 • Areas connected to the river but not in the channel (e.g. backwaters): sandy areas
22 with limited vegetation that provide foraging habitat for plover chicks. Such habitat
23 would be subject to fluctuating water levels but flow velocities may be lower, limiting
24 erosion or supporting deposition; may be associated with pallid sturgeon habitat
25 projects or created specifically for plovers.
- 26 • ESH, attached to the floodplain or not, located in areas not currently managed for
27 sandbar habitat: potential is very limited in channelized portions of the river but
28 some habitat could potentially be formed in association with sturgeon habitat
29 projects.

30 Hydrologically disconnected habitat (e.g. sandpits separated from the river) is not
31 included in this category. Most non-sandbar habitat types are conceived as providing
32 habitat that is either available when most other habitat is not (e.g. during high water) or
33 may will persist longer than ESH due to less exposure to erosive flows. A tradeoff is that
34 habitat that is less affected by river flows than in-channel sandbars will require ongoing
35 and possibly extensive habitat maintenance and predation management in the absence
36 of natural processes that occur on sandbars. Each type of non-sandbar habitat identified
37 now or in the future will be evaluated for effectiveness separately.

1 **Implementation criteria:** To implement pilot projects: TBD To implement at
2 broader scales: TBD

3 **Constraints:** Habitat must be hydrologically connected to the mainstem Missouri
4 River and provide wet sand foraging habitat accessible to plover chicks hatched at the
5 site. Some non-ESH least terns have used for nesting will not be suitable for piping
6 plovers due to lack of foraging habitat. Property ownership and access may limit
7 capabilities to construct/maintain habitat types. Suitable topography and substrate
8 must be available, or costs may increase considerably.

9 **Performance metrics:** Area of suitable habitat (as defined by ESH habitat criteria of
10 suitable substrate and <30% vegetation cover) area of foraging habitat, number of birds
11 nesting at the site, fledge ratios, predation observations.

12 **Human considerations metrics:** TBD; will likely depend upon project type and
13 location.

14 **Uncertainties, research, and active AM:** Data on nesting and brood-rearing
15 success, site selection, and site fidelity on habitat other than sandbars and reservoir
16 shorelines is extremely limited due to the absence of such habitat on the Missouri River.
17 A few sites outside of the ESH-managed segments on the Missouri River have been used
18 for nesting by terns, but not by plovers. Some data exists for hydrologically disconnected
19 habitat on the Central Platte River, but differences in substrate type, groundwater,
20 creation of sites, and the general lack of in-channel habitat in that section of the Platte
21 River limit the ability to consider those sites as analogous to potential alternative habitat
22 creation on the Missouri River. Monitoring data is more limited on the Lower Platte and
23 precludes comparative analysis. The numerical plover and habitat models can be revised
24 to include alternative habitat types, though analyses will be limited by the lack of
25 empirical data. Feasibility studies will be required prior to pilot implementation; a study
26 on the feasibility of created reservoir habitat was previously conducted and estimated
27 low benefit. Pilot-scale projects would need to be evaluated over multiple years to
28 understand habitat suitability, and plover nest site selection and site fidelity over time
29 and relative to a range of potential conditions on the river (e.g. when ESH or reservoir
30 shoreline habitat is abundant vs. when it is scarce.)

31 Information from projects not implemented by the MRRP may be used to address this
32 management uncertainty if sufficient information is collected. At minimum, site area,
33 number of nesting adults, and number of fledglings produced at a site, using the same
34 metrics and definitions as for the MRRP monitoring, is necessary to evaluate action
35 effectiveness. Information on additional management actions (i.e. predator control,
36 vegetation management) including treatment type, level of effort, and/or area treated is

1 also required. Observations of predation rates, nest success rates, dispersal, and site
 2 fidelity are useful and will be included in action effectiveness assessments if available.

3 Table 29. Questions and study summaries for non-sandbar habitat creation research and active AM.

Question	Study Summary	Metrics	Related studies
Management Uncertainty To what extent can non-sandbar habitat creation actions contribute to the success of birds on the Missouri River?			
Associated Hypotheses Non-sandbar habitat creation contributes to the fledgling production and population growth on the Missouri River by providing additional habitat and habitat that may be available at times when ESH and/or reservoir shoreline habitat is not available.			
Non-intervention research studies (Level 1)			
Is <non-sandbar habitat type> creation feasible?	Assessment of site availability, access and suitability, construction requirements and costs; maintenance requirements and costs	Number, location and area of suitable sites; costs	
Are there analogous sites or conditions that provide evidence for the effectiveness of a habitat type?	Assessment of evidence from MRMS and other plover breeding areas	Area of suitable habitat; site selection; site fidelity; adult numbers; breeding bird density; number of fledglings and fledge ratio	
What are the site, region, and population-scale effects predicted by models for a range of habitat creation locations and levels?	Modeling studies using data if available; expert opinion if not (with results indicating the impact of using expert opinion vs. relying solely on existing data)	Fledgling production, number and proportion of birds nesting at alternative habitats, response of population size and viability metrics to number of sites and area of alternative habitat	
Pilot projects and/or field experimentation (Level 2)			
Does a pilot project provide habitat and support fledgling production similar to sandbar or reservoir shoreline habitat in the same region?	Pilot-scale implementation of one or a small number of sites; additional monitoring of sites and nearby sandbar/reservoir shoreline habitat may be required to assess effectiveness; banding to assess site fidelity and dispersal	Area of suitable habitat; site selection; site fidelity; adult numbers; breeding bird density; number of fledglings and fledge ratio; return rates	

4

5 **Criteria for adjusting action:** The process to move from research to pilot projects
 6 and to move from pilot projects to broader or full-scale implementation depends on the
 7 nature of the action and the extent to which it was studied as part of the MRRMP-EIS.
 8 Section 1.1.6 provides an overview of the considerations involved. While some limited,

1 one-time “test flows” might be implemented under the current ROD and Master Manual
2 criteria, the remaining flows evaluated in the EIS would require the release of a new
3 ROD, would need new technical criteria to be accepted for the Master Manual, and may
4 require additional environmental assessment before they could be broadly
5 implemented. Actions outside those evaluated in the EIS would require all the above.
6 Additionally, any acceptance of new actions outside the ROD would follow a high level
7 of collaboration among the agencies and the MRRIC (Section 0).

8 **Decision and collaboration level:** The Management Team allocates budget and
9 other resources to research and pilot-scale implementation activities, based upon
10 recommendations of the Bird Team and the balance of other MRRP needs including
11 pallid sturgeon management activities. The Bird Team and implementation staff decides
12 upon the sites, methodology, and design of construction activities based on best
13 practices and manages contracts and monitoring.

14 **3.2.4.3.2 Reservoir water level management to provide shoreline habitat or**
15 **reduce take on shorelines**

16 **Definition and function:** Reservoir releases expose potential shoreline habitat.
17 Exposed shoreline that was previously inundated for >160 days in the past two years are
18 expected to increase the unvegetated area available for nesting. Increases in reservoir
19 elevation during the nesting season can inundate nests and lower fledgling production
20 on reservoir shorelines. Such increases commonly occur as part of routine operations,
21 particularly in Lake Sakakawea. In contrast, stable or declining reservoir levels during
22 the nesting season can reduce or prevent nest inundation and provide additional
23 foraging habitat.

24 **Implementation criteria:** Reservoirs are not currently managed to provide plover
25 habitat or manage nest inundation. This category includes management modification
26 specifically intended to improve nesting conditions by managing changes in reservoir
27 elevation to provided unvegetated shoreline habitat or by limiting the increase in
28 reservoir elevation during the nesting season. Opportunities exist to manage releases for
29 populations nesting on shorelines while meeting other reservoir management
30 requirements may be identified following the draft MRRMP-EIS.

31 **Constraints:** Maintaining reservoir levels in the optimal storage range and releasing
32 water at rates necessary to support authorized purposes and limit nest/chick take in
33 riverine reaches are currently prioritized over managing for reservoir habitat.
34 Depending on timing, ESH availability and elevation, releases may have downstream
35 impacts on habitat availability or inundate nests. Overall population effects of reservoir
36 management depends upon the relative population size and productivity of birds

1 nesting on reservoir shorelines vs. reaches and between the Northern and Southern
 2 regions.

3 **Performance metrics:** Available shoreline and inundation; plover population size,
 4 fledgling counts, and fledge ratio on reservoir shorelines. Effects on ESH and fledgling
 5 production on riverine segments should also be evaluated.

6 **Human considerations metrics:** TBD; Effects on HC metrics will depend on the
 7 initial elevation of the reservoir prior to any modification of releases, as well as the
 8 changes during the season.

9 **Uncertainties, research, and active AM:** While the general effects of water
 10 elevation changes on plover productivity on reservoir shorelines can be estimated based
 11 on routine operations, the ability and opportunity to manage for desirable reservoir
 12 shoreline habitat metrics while meeting other requirements and having a net positive
 13 effect on plovers is uncertain. Limited modeling conducted to date has shown small
 14 positive effects for birds of “unbalancing” reservoirs to improve shoreline habitat
 15 availability; additional modeling to explore different potential management rules would
 16 be necessary before test actions could be specifically defined. Monitoring of plovers
 17 nesting on reservoirs tends to be less accurate than on river reaches due to the length of
 18 the shoreline that must be surveyed. The ability to understand the effects of shoreline
 19 habitat availability on nesting plovers during normal operations is affected by the
 20 precision and accuracy of that monitoring.

21 Table 30. Questions and study summaries for reservoir water level management research and active AM.

Question	Study Summary	Metrics	Related studies
Management Uncertainty			
To what extent can improving the availability of existing habitat through flows contribute to -population objectives compared to creating new habitat?			
Associated Hypotheses			
Declining reservoir water levels between years and/or steady or declining water levels during the nesting season increases the area of suitable nesting/brood rearing and plover foraging habitat on the reservoirs, thereby increasing fledgling productivity.			
Non-intervention research studies (Level 1)			
Are there options for managing reservoir water levels for shoreline habitat and take reduction that provide net positive benefits to birds and acceptable HC impacts?	Modeling studies to determine potential for managing water levels to improve reservoir habitat; effects on plover productivity (riverine and reservoir) and reservoir use; effects on HC metrics	Reservoir shoreline habitat availability and inundation, ESH availability, plover adult # and fledge ratio, HC metrics TBD	Interactions with modeling for habitat-forming flows, as they also affect reservoir elevations compared to routine operations.
How do plovers respond (site use, dispersal, and fledgling production) to changes in water	Monitoring, potentially with increased effort as needed to ensure sufficient statistical	Reservoir shoreline habitat availability and inundation, ESH	Dispersal/metapopulation studies could inform assessment of site

Question	Study Summary	Metrics	Related studies
elevations on reservoir shorelines?	power to detect effects, banding to monitor site fidelity and dispersal to other segments or non-MR nesting areas	availability, plover adult # and fledge ratio, site fidelity and dispersal	selection, fidelity, and dispersal.
Pilot projects and/or field experimentation (Level 2)			
Does management of reservoir water elevations improve plover nesting on the reservoir and net positive benefits to the population?	Modification of releases within operational flexibility; TBD	Reservoir shoreline habitat availability and inundation, ESH availability, plover adult # and fledge ratio, HC metrics TBD	Flow modifications for other purposes may affect reservoir shoreline habitat; ensure sufficient monitoring on reservoirs to detect effects

1

- 2 **Criteria for adjusting action:** *To move from research to pilot projects:* To be
 3 determined during AM implementation. *To move from pilot projects to broader or full-
 4 scale implementation:* To be determined during AM implementation.

5 **Decision and collaboration level:** Management Team recommendations to
 6 implement test releases must be approved by MRBWMD, who informs MRRIC of intent,
 7 monitors for impacts and reviews after-action assessment with MRRIC. If the
 8 Management Team decides the action should be elevated from test releases to broader
 9 applications, Oversight must approve the proposed changes after consultation with the
 10 MRBWMD and MRRIC.

11 3.2.5 Effects of Pallid Sturgeon Actions on Terns and Plovers

12 Actions for pallid sturgeon generally only affect birds if they modify reservoir
 13 operations. Channel reconfiguration or sediment augmentation activities are separated
 14 geographically from the areas where the vast majority of plovers and terns nest, and
 15 propagation has no mechanism to affect bird habitat or populations. The effects of all
 16 proposed actions (including those not in the Preferred Alternative) are summarized in
 17 Table 31.

18 Changes to reservoir operations in the Upper Missouri River (Fort Peck Dam to
 19 headwaters of Lake Sakakawea) for pallid sturgeon would affect shoreline nesting
 20 habitat on Lake Sakakawea. The degree of the effects would be dependent on releases
 21 from Garrison Dam; adjustments to Garrison releases to accommodate differences in
 22 inflow may in turn affect birds nesting in Garrison Reach or Lake Oahe. A drawdown in
 23 Lake Sakakawea has the potential to affect habitat availability for plovers, but the long-
 24 term effects would depend on the extent of the drawdown and the topography of the
 25 shoreline. The same volume of water would create larger fluctuations in the elevation of

1 a drawn-down reservoir. The effects of any proposed action of this type could be
 2 evaluated with modeling.
 3 Flow modifications for pallid sturgeon in the Lower Missouri River (Fort Randall or
 4 Gavins Point Dam) would have direct effects on ESH availability in the Gavins Point
 5 Reach and could have indirect effects on habitat availability on reservoir shorelines.
 6 Spawning cues have the potential to create ESH, though not necessarily as efficiently as
 7 habitat-forming flows. Flows of lower peak magnitudes have the potential to cause net
 8 erosion of ESH rather than deposition. The second pulse of the spawning cue would
 9 occur during the nesting season and has the potential to inundate nests initiated prior to
 10 the release. As birds may be able to renest after the peak of the flow release, overall
 11 effects on productivity are uncertain. As empirical evidence for bird responses to flow
 12 patterns such as these is not available, the ability to estimate effects of this action
 13 through modeling are constrained and uncertainty is high.

14

15 Table 31. Effects of pallid sturgeon management actions on piping plovers and least terns

Action	In Pref. Alt.?	Geographic overlap*	Direct effect on bird habitat	Direct effect on bird reproduction or survival	Constraints on bird actions (other than budget)	Uncertainty
Alter Flow Regime at Fort Peck	No	Yes, Lake Sakakawea, downstream depending on Sakakawea releases	Positive or negative effects on reservoir shorelines, depending on Lake Sakakawea releases	Depends on relative releases between Fort Peck and Sakakawea, more likely to reduce risk of nest inundation on shoreline	No	Medium
Temperature Control, Fort Peck	No	No	No	No	No	Low
Sediment Augmentation at Fort Peck	No	No	No	No	No	Low
Passage at Intake	Yes	No	No	No	No	Low
Upper Basin Propagation	Yes	No	No	No	No	Low

Action	In Pref. Alt.?	Geographic overlap*	Direct effect on bird habitat	Direct effect on bird reproduction or survival	Constraints on bird actions (other than budget)	Uncertainty
Drawdown Lake Sakakawea	No	Yes, Lake Sakakawea	Decrease in overall shoreline availability, but sufficient habitat may remain, depending on topography and population size. Increase to extent of inundation when reservoir fills.	No	No	Medium
Alter Flow Regime at Gavins Point, spawning cue	No, but potential for flow test after 9 years	Yes, Gavins Point, Lake Sakakawea, Lake Oahe	Spawning cues of sufficient length and duration create ESH. Lower pulses may erode ESH. Above-normal releases provide additional reservoir shoreline habitat.	Rises beginning in mid-late May may inundate nests. Birds may be able to renest after peak of pulse, depending on timing and subsequent releases	Use of storage could limit ability to implement flow modifications specifically to create ESH	High
Alter Flow Regime at Gavins Point, low summer flows	No	Yes, Gavins Point, Lake Sakakawea, Lake Oahe	Decreased flows in summer increase availability of existing ESH. Decreased releases from Gavins may result in inundation of nests on reservoir shorelines.	Low flows may increase foraging habitat availability and improve chick survival; if releases must be increased, nests or chicks may be inundated.	If water stored during low flows is released in the fall at discharges >35 kcfs, ESH construction, modification, or vegetation removal may be impeded	Medium
Temperature management, Fort Randall	No	Yes, Fort Randall Reach and Gavins Point Reach	No	Might improve prey availability/quality for plovers or terns	No	Medium
Interception and Rearing Complexes	Yes	No	Limited evidence of opportunistic use of existing sturgeon habitat projects for nesting by terns	Possible positive impact if birds nest in areas associated with IRCs	No	Medium
Spawning Habitat	Yes	No	No	No	No	Low
Propagation Lower Basin	Yes	Yes	No	No	No	Low

1

- 2 Actions for pallid sturgeon create few conflicts or additional constraints (aside from budget allocation) on bird management actions. Storage used for a spawning cue flow

1 would be unavailable for a specific ESH-creating flow modification. Any lowered
2 summer flow for fish, as with those designed for birds, could result in held-back water
3 that would need to be released in the fall; if releases exceed ~35kcfs from Gavins Point
4 they may preclude or interfere with ESH creation, modification, or vegetation removal
5 activities (fall releases of sufficient magnitude or duration may create ESH).

6 **3.3 Monitoring**

7 Annual monitoring of habitat and species performance metrics, and as-needed
8 monitoring of action effectiveness experiments and of unusual events will be required to
9 adaptively manage plovers and terns. Monitoring is necessary for tracking program
10 performance relative to targets and identifying trends that indicate a need for changes to
11 management; it also provides some of the information needed to develop and maintain
12 accurate models (e.g. fledgling production relative to habitat availability; changes in
13 ESH availability as a function of river flow). Monitoring requires flexibility and
14 responsiveness to ensure timely and consistent data collection in a highly variable
15 system. As habitat and populations on the Missouri River have the potential to change
16 rapidly, monitoring for performance metrics must occur annually. Information needs
17 that are not addressed through the monitoring program may need to be addressed
18 through focused research.

19 The following priorities have been suggested for ESH and bird monitoring. Monitoring
20 should:

- 21 1. Provide information to continue advancing the habitat and population models for
22 decision support;
- 23 2. Provide information for the evaluation of action effectiveness, including the
24 population response;
- 25 3. Track the habitat and population performance metrics annually to determine
26 whether targets are being met;
- 27 4. Provide information for assessing incidental take;
- 28 5. Be cost effective and practical to implement; and
- 29 6. Be comparable with previous monitoring programs to the extent possible while
30 meeting objectives 1-5.

31 Continued use of the models requires the ability to:

- 32 1. Estimate population size, change, and density over time and space
- 33 2. Estimate fledgling productivity by habitat condition and over time and space
- 34 3. Estimate survival and dispersal over time and space
- 35 4. Quantify management action effects and 'take' annually

1 5. Estimate observation error which may vary by year and segment
2 Information needs for action effectiveness and model development may also be
3 addressed through research, but some information, such as survival or dispersal data
4 requires multiple years of data collection to estimate parameters and additional years to
5 improve accuracy, including such monitoring annually may provide sufficient value over
6 shorter-term research to justify the associated expenses. Tradeoffs will exist between
7 cost effectiveness and information breadth and quality. Initial and ongoing analyses of
8 the statistical power of a monitoring program and the value of information provided will
9 assist with decisions about how to allocate resources to monitoring and other needs.

10 **3.3.1 Monitoring of hydrology and habitat metrics**

11 Hydrological metrics (reservoir releases and pool elevations for Lake Sakakawea, Lake
12 Oahe, Lake Francis Case and Lewis and Clark Lake; flow at Sioux City) are monitored
13 and reported daily by USACE Water Management and provide information for
14 estimating reservoir habitat availability, adjusting ESH estimates, determining
15 incidental take risk and providing historical inputs to use in ESH model validation.

16 ESH is monitored by acquiring satellite imagery of all riverine habitat during the nesting
17 season. Imagery is classified to land cover type, which can then be used to estimate area
18 of ESH (dry and wet sand with less than 30% vegetation cover) and vegetated sandbar.
19 These estimates must be adjusted to standardized and maximum July flows for
20 quantification of standardized and available habitat. Ideally, multiple acquisitions are
21 made, including in May during nest initiation and in July during peak chick production,
22 to more accurately estimate metrics.

23 ESH quantification has been limited to estimating habitat quantity rather than quality.
24 Aside from percent vegetation, no other habitat characteristics are considered in the
25 quantification. Work initiated in the EA to develop a protocol for estimating quality of
26 habitat based upon land cover and landscape features at relevant scales will be
27 evaluated for use in AM. Quality assessments would allow for more accurate predictions
28 of bird population dynamics and better allocation resources to habitat construction or
29 modification. As ESH is quantified with satellite imagery and archived, it can be
30 retroactively reassessed if improvements are made in the quantification and quality
31 assessment protocols.

32 Periodic assessments of channel form using LiDAR and bathymetric surveys are
33 valuable for determining discharge-area relationships needed to accurately estimate
34 standardized and available ESH from imagery collected at different flows and to predict
35 the effects of planned flow releases on habitat availability. Assessments of sediment load

1 should also be conducted. While annual collection of this data may not be necessary,
2 significant changes to channel form, warrants additional data collection. This may be
3 considered periodic monitoring rather than research, in order to regularly update the
4 ESH discharge-area models and provide information for improving the ESH dynamics
5 model.

6 Reservoir habitat is not currently monitored beyond hydrological metrics. Research on
7 metrics for reservoir habitat beyond the hydrological metrics described above would
8 help determine if different or additional metrics should be used to quantify reservoir
9 habitat for predicting bird productivity.

10 **3.3.2 Existing program for monitoring of population metrics and associated
11 challenges**

12 Population monitoring requires adult surveys and monitoring of plover nests and chicks
13 on both riverine and reservoir habitat. Adult counts are needed for estimating
14 population size and growth rate, fledge ratios, and population density. As such, count
15 accuracy is vital, but challenging for mobile species that can be spread across large
16 areas, especially on reservoir shorelines, and fly to forage away from nesting sites.

17 From 1993-2016, the adult population of terns and plovers has been determined by
18 conducting an adult census, an attempt to completely count all adult least terns and
19 piping plovers observed during the third week in June. It is assumed that both of the
20 species are settled on the breeding grounds by that time. There are limitations in trying
21 to accurately count all adult birds on the system, however, due to movement of adult
22 birds, and so the adult count is augmented on sites where the number of adults counted
23 is less than two times the number of active nests and broods at that site. The timing of
24 the adult count – the third week in June – also raises some concerns. The USGS in their
25 analysis of the USACE Tern and Plover Monitoring Program (TPMP; Shaffer et al. 2013)
26 found that peak adult numbers varied by species, by segment and by year, yet none of
27 that variability is factored into the adult census methodology. Since the total number of
28 adults is a key component in calculating the fledge ratio, the USACE should evaluate
29 alternative methods to determine the total number of adults for the monitoring
30 program.

31 Fledgling counts are required for estimating fledge ratios and density-productivity
32 relationships. Fledge ratios have been used by the USFWS to assess take of least tern
33 and piping plover eggs, chicks, and adults by factors influenced by but not directly
34 attributable to the USACE (predation, human disturbance, abandonment, and erosion),
35 and to assess take of piping plover chicks as a result of insufficient forage in river
36 reaches affected by hypolimnetic releases or on created habitats. The use of fledge ratios

1 in assessing take in the future will be addressed in the Incidental Take Statement
2 accompanying the new BiOp. Fledgling monitoring generally has higher detection and
3 accuracy than adult monitoring (Shaffer et al. 2013), as chicks can be more easily
4 observed and counted prior to fledgling, but requires repeated visits to determine
5 whether chicks survive to fledge. The USACE method of determining fledglings
6 combines counting actual fledglings (chicks able to fly) and assumed fledglings (plover
7 chicks observed in the 21-24 day age group and tern chicks observed in the 16-20 day
8 age group, but not seen as fledglings). However, the ability to observe chicks and
9 determine fledglings is weakness of the TPMP. The cryptic coloration of chicks makes
10 them difficult to observe, and with a 7-10 day return interval for monitoring, some
11 chicks are never observed. In addition, it is difficult to ascertain whether the fledglings
12 observed at a site are chicks that just fledged, fledglings previously observed on site, or
13 chicks that fledged elsewhere and are using the site as a stopover area. The USACE
14 should evaluate alternative methods to determine the total number of fledglings at a
15 site.

16 While not a direct performance metric for AM, monitoring of nests and broods has also
17 been conducted to assess and avoid take in coordination with water management.
18 Monitoring of nests and broods can provide some information as to the degree of
19 predation, human impacts, and other causes of egg/chick mortality, and improves
20 accuracy of fledgling counts. Such information is useful for understanding observed
21 population dynamics and to trigger and assess effectiveness of population protection
22 actions, but causes of mortality cannot always be determined and nest detection can be
23 low, particularly for failed nests. Accurately determining nest fate relies on the ability of
24 the crew to find the nest and revisit it frequently enough to determine the outcome. The
25 USGS analysis of the monitoring program identified problems related to the ability to
26 find nests and determine nest fate, including the late start of the monitoring program
27 (typically mid-May), the frequency of nest visits (typically 7 – 10 days), and the ability to
28 detect nests at any given site (Shaffer et al. 2013). The monitoring program needs to be
29 flexible enough to adapt to changes in habitat availability and increase crew size
30 accordingly in order to more effectively survey sites and reduce the return interval. The
31 program also needs to address the shortfall in monitoring early season nesting activity.

32 Accuracy of the monitoring program varies depending on habitat area that must be
33 surveyed, population density, habitat type and age, and experience of monitoring crews.
34 Thus accuracy can vary by year and by segment, and with the exception of Shaffer et al.
35 2013, has not been quantified in the past. Recommendations to address this challenge
36 are under consideration and future versions of the AM Plan will include any refinements
37 to monitoring procedures.

- 1 The monitoring program must be robust to changes in budget or staffing availability, or
2 prioritized such that a base level of monitoring can always be performed at an adequate
3 level. Fluctuations in level of effort and quality of monitoring, such as may occur when
4 funding, equipment or personnel resources are limited, affect both near-term decision
5 making and longer-term assessment of trends and hypothesis assessment.
- 6 The predictive habitat and population models will be used to assess the effects of
7 estimated monitoring error and bias on assessment of population objectives.
8 Adjustments may be identified and applied to target metrics to accommodate known
9 limitations in the monitoring program [details to be determined following updates
10 and/or changes to the monitoring program]. They will also be used to assess proposed
11 changes to the monitoring program to evaluate robustness to changing habitat
12 conditions and funding/staff availability.
- 13 Periodic review of the monitoring program (e.g. on a 5-year basis) will occur to assess
14 adequacy. If necessary, improvements should be made while keeping in mind that
15 changes to protocols affects the ability to compare data collected before and after the
16 changes are made. Similarly, if methods of collecting information more quickly or cost-
17 effectively become available, they should be explored, but potential impacts to
18 assessment caused by changes to monitoring protocols should be taken into account
19 before changes are made.

20 **3.3.3 Options for changing the population monitoring program**

21 Development of this AM plan, including changes in the piping plover targets,
22 monitoring priorities, and use of the AM models provide an opportunity to re-evaluate
23 the Tern and Plover Monitoring Program (TPMP), which has several challenges outlined
24 in the previous section. Going forward, several options are being considered to improve
25 the monitoring program following the priorities and model data needs listed at the
26 beginning of section 3.3.

27 **Option 1: piping plover monitoring program with a bird banding and re-
28 sighting focus to estimate the piping plover breeding population and
29 fledgling population**

30 This option includes a monitoring program with marked birds (chicks and adults),
31 spatial sampling, error estimation, and productivity represented by fledglings and their
32 recruitment to the breeding population. Use of a marked population and spatial
33 sampling will provide additional data to estimate annual movement, recruitment, and
34 survival (metrics for model parameterization).

- 1 The focus on breeding adults at nests will provide an idea of the proportion of piping
 - 2 plover nests loss (including incidental take) during a field season but not directly
 - 3 measure overall take.
- 4 Note: Least terns will be monitored following the Post-delisting Rangewide Monitoring
 - 5 Protocol for Interior Least Terns (USFWS; in draft).
- 6 The program would estimate:

- 7 • **Population size**—estimated annually with open population models
- 8 • **Population change**—estimated using annual population size estimates
- 9 • **Population density**—estimated using annual population size estimates and
- 10 estimates of emergent sandbar habitat
- 11 • **Productivity**—population of fledged young estimated using open population
- 12 models and marked fledglings

13 14 Requirements:

15 Banding the population

- 16 • Segments (reservoir & river segments) include Lake Sakakawea, Garrison River,
- 17 Lake Oahe, Fort Randall River/ Lewis & Clark Lake, Gavins Point River.
- 18 • 50-100 adult piping plovers marked per segment annually.
- 19 • 100-200 piping plover chicks marked per segment annually.
- 20 • Five banding teams cover all segments.

21 22 Spatial sample

- 23 • Classify segments of each segment as low, medium, or high use by nesting
- 24 plovers.
- 25 • Select a portion of habitat in each segment to visit.
- 26 • Monitoring crews locate nests and place trap cameras at nests in segments.
- 27 • The same crews later re-sight birds; personnel numbers are about the same as
- 28 historically used for the TPMP survey.

29 30 TPMP Option 1 Methods:

- 31 1. Stratify sampling units. In week one, survey a set number of high/medium quality
- 32 sampling units 3 times (M,W,F) and survey a set number of low quality sampling
- 33 units 2 times (Tues, Thu). In week two, survey a different set of high/medium and
- 34 low quality sampling units. Repeat the pattern so that in week 3, crews are back to

1 the same set of units surveyed in week 1; and in week 4, crews are back to the same
 2 set of units surveyed in week 2. On the river segments, 2 crews of 2-3 people are
 3 required. On the reservoir segments, 3 crews of 2-3 people are required.

4 Table 32. Sample outline of monitoring schedule by week and unit for river segments.

river segment example					
Week 1	Monday	Tuesday	Wednesday	Thursday	Friday
Crew 1 (2 people) cover 4 sample units	2 hi/med sample units	2 low sample units	2 hi/med sample units	2 low sample units	2 hi/med sample units
Crew 2 (2 people) cover 4 sample units	2 hi/med sample units	2 low sample units	2 hi/med sample units	2 low sample units	2 hi/med sample units
Week 2					
Crew 1 (2 people) cover 4 sample units	2 hi/med sample units	2 low sample units	2 hi/med sample units	2 low sample units	2 hi/med sample units
Crew 2 (2 people) cover 4 sample units	2 hi/med sample units	2 low sample units	2 hi/med sample units	2 low sample units	2 hi/med sample units
Repeat through the nesting season; i.e. in week 3 –crews return to week 1 sample units, in week 4 – crews return to week 2 sample units, etc. for a total of 8 sample units monitored throughout the breeding season.					

5

6 Table 33. Sample outline of monitoring schedule by week and unit for reservoir segments.

reservoir segment example					
Week 1	Monday	Tuesday	Wednesday	Thursday	Friday
Crew 1 (2 people) cover 10 sample units	5 hi/med sample units	5 low sample units	5 hi/med sample units	5 low sample units	5 hi/med sample units
Crew 2 (2 people) cover 10 sample units	5 hi/med sample units	5 low sample units	5 hi/med sample units	5 low sample units	5 hi/med sample units
Crew 3 (2 people) cover 10 sample units	5 hi/med sample units	5 low sample units	5 hi/med sample units	5 low sample units	5 hi/med sample units
Week 2					
Crew 1 (2 people) cover 10 sample units	5 hi/med sample units	5 low sample units	5 hi/med sample units	5 low sample units	5 hi/med sample units
Crew 2 (2 people) cover 10 sample units	5 hi/med sample units	5 low sample units	5 hi/med sample units	5 low sample units	5 hi/med sample units
Crew 3 (2 people) cover 10 sample units	5 hi/med sample units	5 low sample units	5 hi/med sample units	5 low sample units	5 hi/med sample units

Repeat through the nesting season; i.e. in week 3 –crews return to week 1 sample units, in week 4 – crews return to week 2 sample units, etc. for a total of 60 sample units monitored throughout the breeding season

1

- 2 2. Locate nests at designated sampling units, GPS the nest location, and place “trap
- 3 cameras” (such as the Kodak PixPro video cameras) at nests with a full clutch for a
- 4 minimum of 30 minutes.
- 5 3. Identify adults on nests (marked and unmarked); do not re-sample nests where
- 6 adults have already been videotaped.
- 7 4. Starting in mid-June crews start carrying digital cameras & take pictures of
- 8 fledglings in addition to setting trap cameras. Record the number of marked and
- 9 unmarked fledglings.
- 10 5. Population size is estimated by segment and sample period using a mixed logit-
- 11 normal mark-resight model.
- 12 6. Stratification may change annually; should sample at least 25% of each study
- 13 segment.
- 14 7. Crews are not carrying scopes, grid searching, tracking eggs or chicks.
- 15 8. Nest success, egg numbers are not tracked.
- 16 9. Incidental take estimates would be limited, since nest success is not tracked.

17 **Option 2: piping plover monitoring program without a bird banding and re-**
18 **sighting focus**

- 19 Includes a monitoring program with spatial sampling, error estimation, and
20 productivity represented by observed fledglings. Use of spatial sampling will provide
21 additional data to estimate observation error.
- 22 The focus on monitoring nests will provide an idea of the proportion of piping plover
23 nests loss (i.e. ‘take’) during a field season.
- 24 Note: Least terns will be monitored following the Post-delisting Rangewide Monitoring
25 Protocol for Interior Least Terns (USFWS; in draft).

26 **TPMP Option 2 Methods:**

- 27 1. Stratify sampling units and sample using the same monitoring schedule as described
- 28 in Option 1.
- 29 2. During each visit, find, mark (GPS), and count nests. Conduct repeat (3) visits
- 30 within a time-period. Repeat this process throughout the breeding season.

1 3. Age-ratios could be used to assess recruitment for populations of unmarked birds;
2 assuming constant detection, annual changes in age-ratios (hatch year : after hatch
3 year individuals) can reflect changes in productivity.

4 4. Starting in mid-June, TPMP crews count the number of fledgling-aged chicks and
5 the number of adults on each surveyed segment.

6 5. Measurements of estimation error will be possible due to repeat site visits.

7 6. The Minimum Breeding Population (MINBPOP) will be calculated to determine
8 adult numbers (in lieu of an adult “census”). The number of breeding plover pairs is
9 estimated from the daily sum of active nests plus all previously hatched nests plus
10 nests failed during incubation within the previous 5 days. This estimate represents
11 the minimum number of breeding pairs that used each sampling unit and provides a
12 relative distribution of breeding pairs on each unit within each reach.

13 7. Benefits of this method include:

14 a. estimates of population size with error

15 b. estimates of productivity with error

16 c. Shorter intervals between nest searches mean less opportunity for nests to fail
17 without being discovered and increased opportunity to locate nests that
18 ultimately produce hatchlings.

19 d. Shorter intervals also lead to fewer errors in nest fate determinations and in
20 assigning causes of nest failure.

21 e. Shorter intervals may also result in increased chick observations, which could
22 improve fledgling estimates.

23 8. Drawbacks of this method include:

24 a. ‘other’ demographic estimates (e.g. movement, recruitment, survival) not
25 possible

26 b. limited ability to understand ‘why’ population changes are occurring

27 c. limited ability to assess management action effects with some certainty

28 d. like the previous method, not all incidental take will be documented

29 e. index of productivity is based on observation of chicks and fledglings

30 f. double-counting adults and chicks will continue to be problematic

31

32 Other monitoring options are being considered and the monitoring protocol will be
33 finalized in the final AM Plan.

34 **3.3.4 Additional species monitoring**

35 Depending on the final design of the monitoring program, additional information may
36 be needed about species demographics, dispersal, and/or habitat use. Supplemental
37 monitoring programs, research, or collaboration with other programs could be used to

1 supply the needed information. The MRRP can benefit from cooperation with other
2 programs that mark and/or resight birds in wintering habitat and other breeding areas.

3 **3.3.5 Action effectiveness monitoring and research**

4 The types of additional monitoring required for action effectiveness depends upon the
5 action and the degree to which existing monitoring is sufficient. Systematic actions such
6 as flow modifications require monitoring data on a different scale than site-specific
7 actions which may only require information from a small number of sandbars within a
8 single reach. Some management hypotheses can be evaluated with existing monitoring,
9 but others may need supplemental or more focused monitoring in specific areas. For
10 example, bird use and fledgling success on constructed sandbars compared to naturally-
11 created sandbars can be assessed using the same ESH monitoring and bird productivity
12 monitoring data collected for evaluating system-wide performance metrics, but may
13 require sandbars to be added to the sampling design used for routine monitoring. Other
14 information needs for routine monitoring may include:

- 15 • Habitat-forming flow releases: additional imagery and delineation of habitat
16 availability directly after flow release (especially for fall flow releases); elevation
17 surveys to determine elevation profiles of created sandbars; field surveys to track
18 evolution of created sandbars.
- 19 • Lowered nesting season flow releases: ensure habitat quantification captures
20 availability during release; assessment of ESH area before and after flow and after
21 fall evacuations of extra storage to evaluate effects on erosion.
- 22 • Sandbar augmentation and modification: elevation surveys and other field
23 observations to evaluate effectiveness, longevity, and evolution of modifications,
24 comparison of wet to dry sand ratio pre and post modification.
- 25 • Vegetation management: Line intercept sampling on sandbars using a BACI designed
26 experiment. See line intercept protocol Attachment #4, Appendix G; Spatial analysis
27 using land cover classifications should be used when available but may have
28 limitations in detecting changes due to imagery resolution
- 29 • Predation management/human restrictions: Focused monitoring (e.g. increased use
30 of cameras) of selected locations where actions are implemented, in contrast with
31 controls, to detect effects of actions on nest success.

32 The need for action effectiveness monitoring diminishes with time as information is
33 collected and uncertainty decreases. The uniqueness and value of additional
34 information, in relation to the monitoring cost, should be assessed before determining
35 additional monitoring requirements. E.g. high flows happen rarely and under unique
36 conditions, so additional information would likely be valuable for most releases, and
37 worth some cost to understand the relative value of flow actions compared to

1 construction and any resulting impacts. In contrast, the effectiveness of sandbar
2 construction projects is fairly well understood. Effectiveness assessment of routine, non-
3 experimental construction could be done at little to no cost through existing monitoring.

4 **3.3.6 Events requiring additional monitoring**

5 Natural events provide valuable information for evaluating management actions and for
6 understanding natural variability. Of particular interest include reservoir releases out of
7 the normal range and their effects on habitat dynamics and bird productivity.
8 Monitoring would include geomorphic assessments like those described above for
9 tracking action effectiveness and bird responses. Survival and dispersal data will be
10 especially valuable during unusual conditions (such as very high or low habitat
11 availability, coupled with habitat conditions in other breeding areas).

12 Actions conducted for pallid sturgeon management that affect plovers and terns are
13 primarily flow modifications (see Section 3.2.5). Their effects on ESH dynamics and
14 fledgling production will be monitored and assessed in the same way as flow
15 modifications conducted specifically for birds. The effects of spawning cue releases on
16 ESH would provide valuable information for the ESH model. The effects of a spawning
17 cue pulse after mid-May on nesting success are uncertain; additional monitoring during
18 and shortly after the flow may be warranted.

19 **3.3.7 Monitoring and research to improve models and action planning/design**

20 Focused studies geared to specific predictive modeling information needs should be
21 regularly assessed and incorporated into the monitoring and research program. For
22 example, the ESH models would benefit from the following studies:

- 23 • Investigation of alternative timeframes over which conditions are averaged to
24 determine which provides the most accurate and useful (these are not necessarily the
25 same) basis for the ESH models.
- 26 • Monitoring of typical, unusual, and experimental flows would provide needed data
27 that, with statistical and regression analyses, provides a means to update the flow-
28 ESH relations and refine estimates of variability and error.
- 29 • High-fidelity studies of sandbar morphodynamics already undertaken in the Gavins
30 Point reach should be revisited and extended to include the other reaches. The
31 resulting data provides a) an improved understanding of underpinning processes of
32 sandbar growth and decay, b) a basis for enhancing the stage-area relations, and c) a
33 basis for establishing multi-dimensional models of bar processes to initially
34 supplement and eventually replace the existing models.

- 1 The bird population models would benefit from studies such as the following, in
2 addition to surveillance information on adult and fledgling numbers and
3 demographic rates, as described above:
4
- 5 • What habitat quality characteristics affect plover reproduction and chick survival?
 - 6 • What are the differences in reproductive performance among geographic locations, if
7 any? What are the management implications?
 - 8 • Does plover site fidelity change as habitat degrades? Does site fidelity have
9 implications for decisions such as where to construct a sandbar or which sandbars
10 should be treated for vegetation or mechanically modified?
 - 11 • What constitutes an adequate forage base? Do changes to plover condition based on
12 food quality/availability affect fledge ratios or survival?
 - 13 • What effect does variability in water elevation, including power peaking, have on
14 plover prey abundance and availability and resulting fledgling production?
- 15 The value of potential studies can be addressed by estimating the cost savings provided
16 by reduced uncertainty and improved accuracy in predictive models used to calculate
17 habitat and other management needs. Uncertainty compels managers to manage in
18 ways that hedge against worst-case scenarios; more accurate and precise estimates of
19 likely outcomes leads to more efficient management.

3.4 Implementation

21 Implementation of management actions for the birds is generally described in the
22 preceding sections. Some evaluations may be ongoing during implementation, as
23 described in the following section. [Note: further discussion of the implementation step
24 may be provided in the final AM Plan].

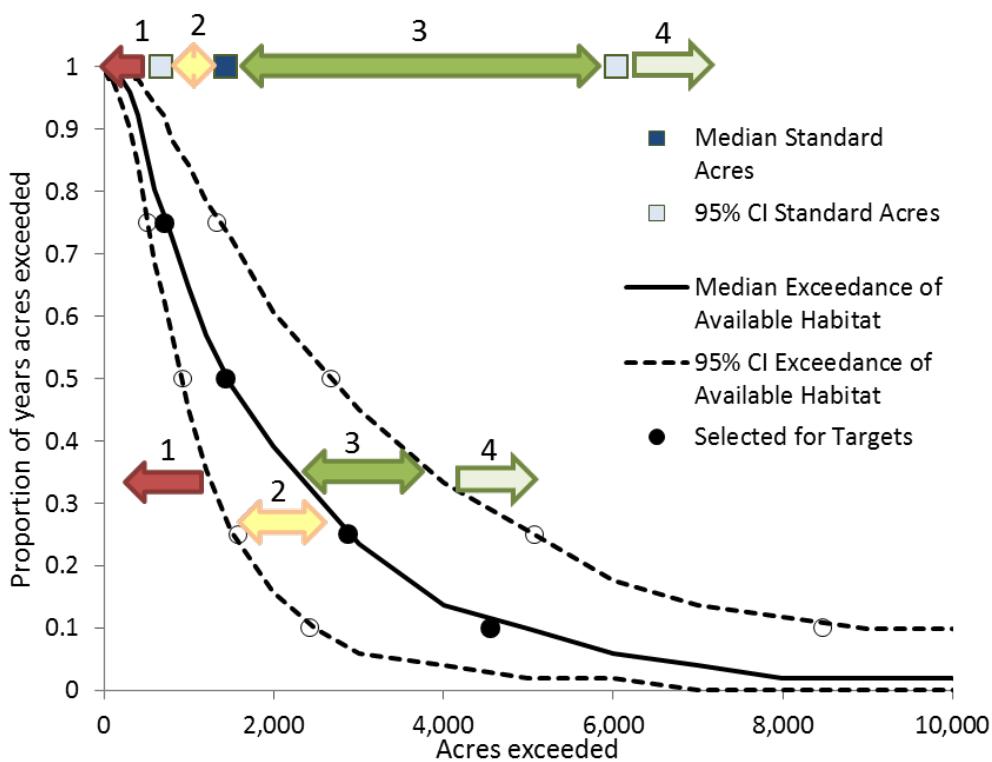

3.5 Evaluation

26 The Evaluation step is primarily conducted by the Technical Team, which coordinates
27 with the Bird Team to obtain information and identify analytical needs. The Technical
28 Team's analyses begin as monitoring data becomes available in fall. The Fall Science
29 Meeting is the venue to review initial outcomes of the previous year's management
30 actions, monitoring, and research, and to identify specific analytical topics of interest to
31 the Management Team, Bird Team, and MRRIC Bird WG. The Technical Team conducts
32 routine annual analyses as described in this section, assesses topics identified as
33 priorities by the other teams, and presents results in the Draft AM Report. As illustrated
34 in (Figure 16) the Draft AM Report is reviewed in the AM Workshop, revised, and
35 released as a final draft in the spring. This process and the AM Report is the primary
36 means for developing and communicating the technical information for the MRRP, but
37 additional evaluation tasks may arise at other points in the year for topics needing

1 immediate assessment or for longer-term assessments that cannot or do not need to be
 2 completed during the annual cycle. Annual analyses include evaluation of status and
 3 conditions, hypothesis evaluations, and model updates and validation. The process
 4 allows for inclusion of ancillary information and assessment of unexpected outcomes.

5 3.5.1 Evaluation of habitat status relative to targets

6 ESH targets are expressed as a quantity of standardized ESH, to be met 3 out of 4 years,
 7 and as a distribution over time of available ESH, as described by the proportion of the
 8 most recent 12 years in which available ESH should exceed specified acreages. Both
 9 standardized and available ESH are specified by median and 95% confidence intervals.
 10 The medians provide the target requirements, but the confidence interval allows for
 11 variability around that goal driven by the uncertainty in future flows and variability in
 12 species response. Species-habitat dynamics are not perfectly known, so more or less
 13 ESH than the median estimate may be needed to meet demographic targets. Observed
 14 acreages that fall outside the confidence interval should result in more intensive changes
 15 to action plans than acreages that fall within the confidence interval. There are four
 16 possible outcomes (Figure 46) when comparing observed ESH to targets, each
 17 suggesting a course of action:

18

19 Figure 46. Standardized (squares) and available acreage exceedance targets (circles) with confidence bounds
 20 (light blue squares, dashed lines). Observed habitat acreages can fall within four numbered regions relative to
 21 the acreage bounds, as described in the text.

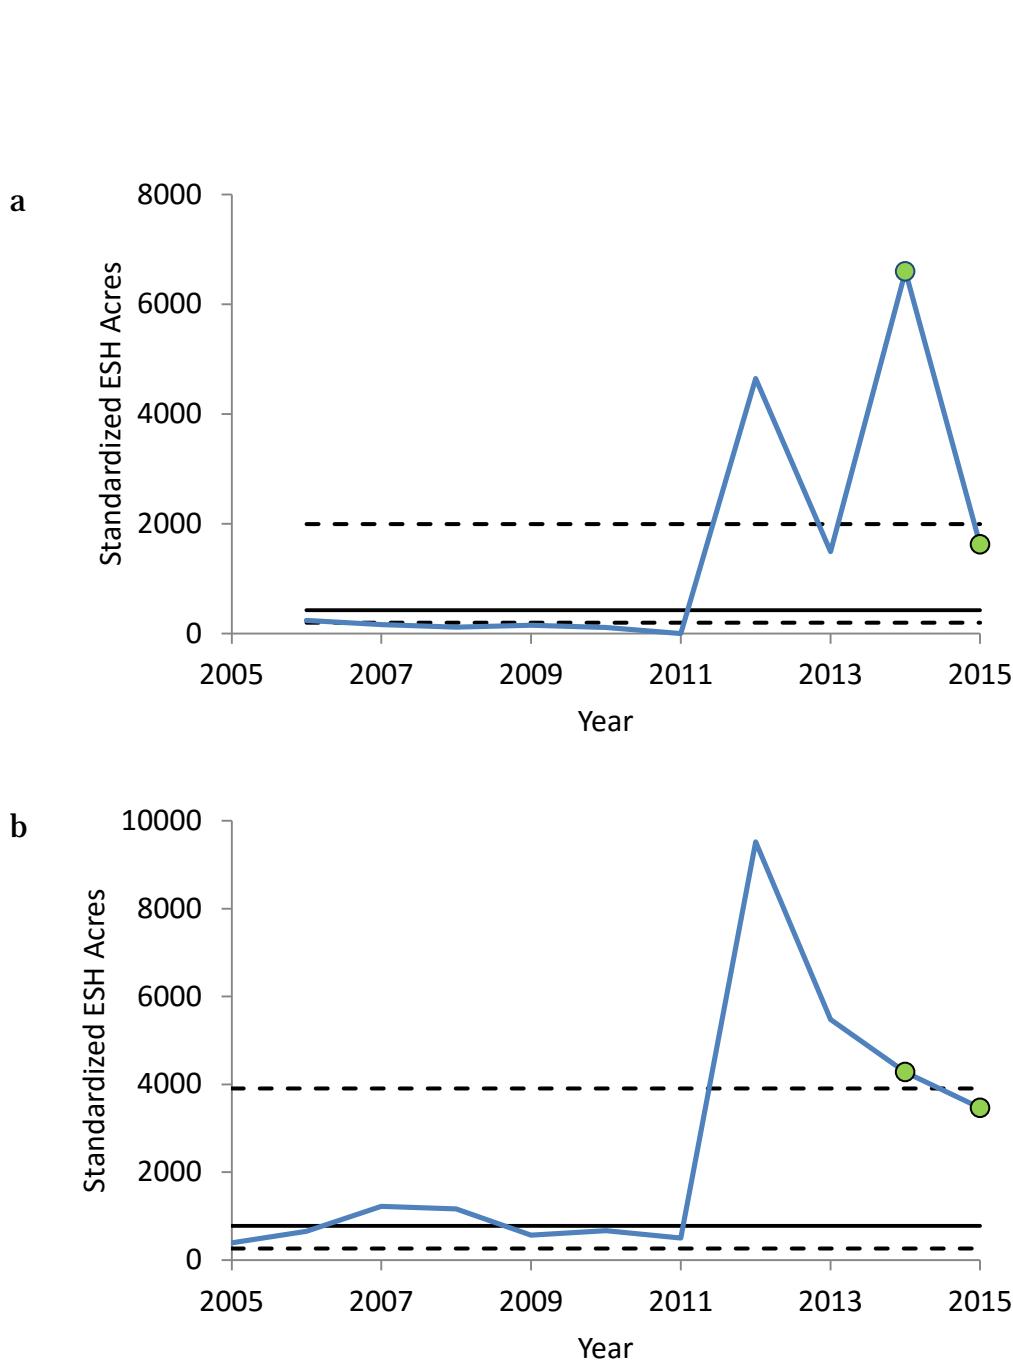

- 1) The acreage is below the lower confidence bound. It is very unlikely that populations have enough ESH to meet objectives and the pace of habitat creation must increase.
- 2) The acreage is below the median and above the lower confidence bound. While it is possible that population dynamics will meet objectives, habitat creation to increase ESH to median levels is needed.
- 3) The acreage is above the median and below the upper confidence bound. In this case, it is possible but not certain that more habitat is available than necessary to meet population objectives. Habitat should be maintained with new habitat creation focused on ensuring acreage does not drop below the median.
- 4) The acreage is above the upper confidence bound. It is very likely there is more habitat than is necessary to maintain the desired species status. Habitat creation is not needed, though existing ESH should be maintained.

For available habitat, the comparison to targets is similar, but requires evaluation of habitat availability over 12 years to create the exceedance curve. That curve is compared to the target and the associated confidence intervals in the same way as the standard acreage (Figure 46). Exceedance curves take time to respond to change in management practices due to the longer time frame. The upper end of the exceedance curve (10% exceedance) may only be met following flows high enough to create habitat.

ESH targets are defined for the Northern and Southern Region and should be evaluated for each region separately (Table 34). In Figure 47 and Figure 48, ESH data from 2006-2015 are compared to the standardized ESH targets and the target exceedance for available ESH. Median standardized ESH targets were exceeded from 2012-2015 for the Northern Region and for 2007-2008 and 2012-2015 for the Southern Region. The timeframe of 3 out of 4 years exceeding the median target was met in 2014 and 2015 for both regions. The habitat availability target has been met for both regions (the observed exceedance line is to the right of the median target line.) Observed ESH compared to habitat availability targets is above target for all percent exceedance metrics (Figure 48).

Table 34. Target and observed available habitat exceedance proportions and acreages (2006-2015). Targets are met if the observed acres exceeded are greater than the median target acres, within each row, for each region. Likewise, the observed exceedances are greater than the target exceedances. Shaded cells indicate the target is met.

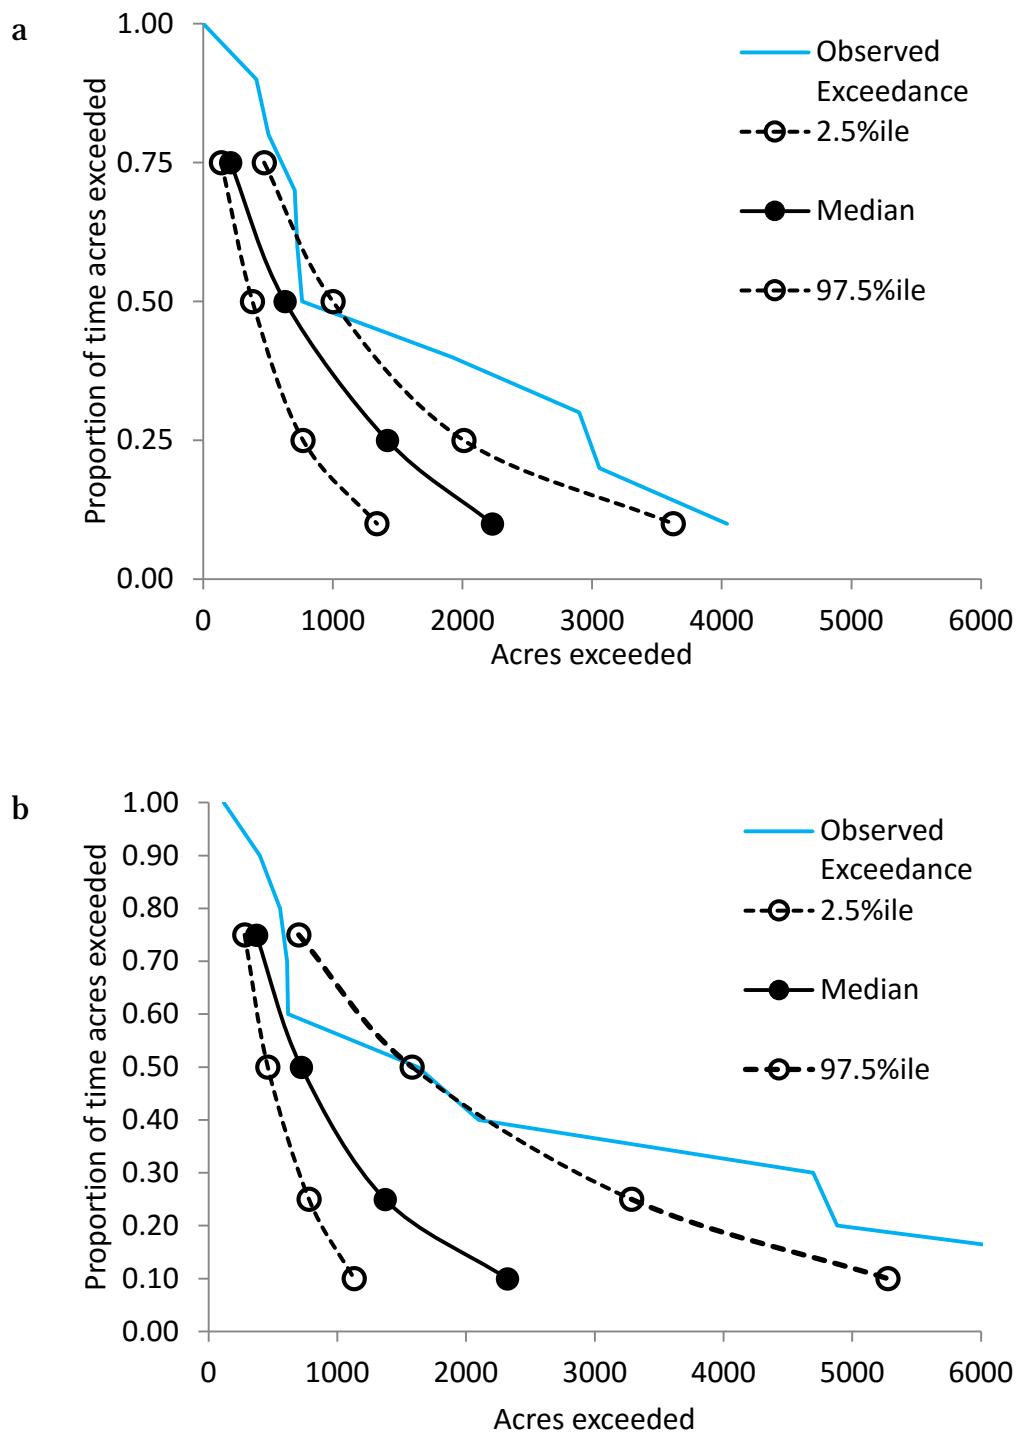

Southern Region				Northern Region			
Target exceedance	Observed acres exceeded	Median target acres exceeded	Observed exceedance	Target exceedance	Observed acres exceeded	Median target acres exceeded	Observed exceedance
75%	540	370	90%	75%	503	210	90%
50%	1627	720	50%	50%	763	630	70%
25%	4695	1370	50%	25%	2900	1420	40%
10%	4880	2320	30%	10%	3057	2230	30%

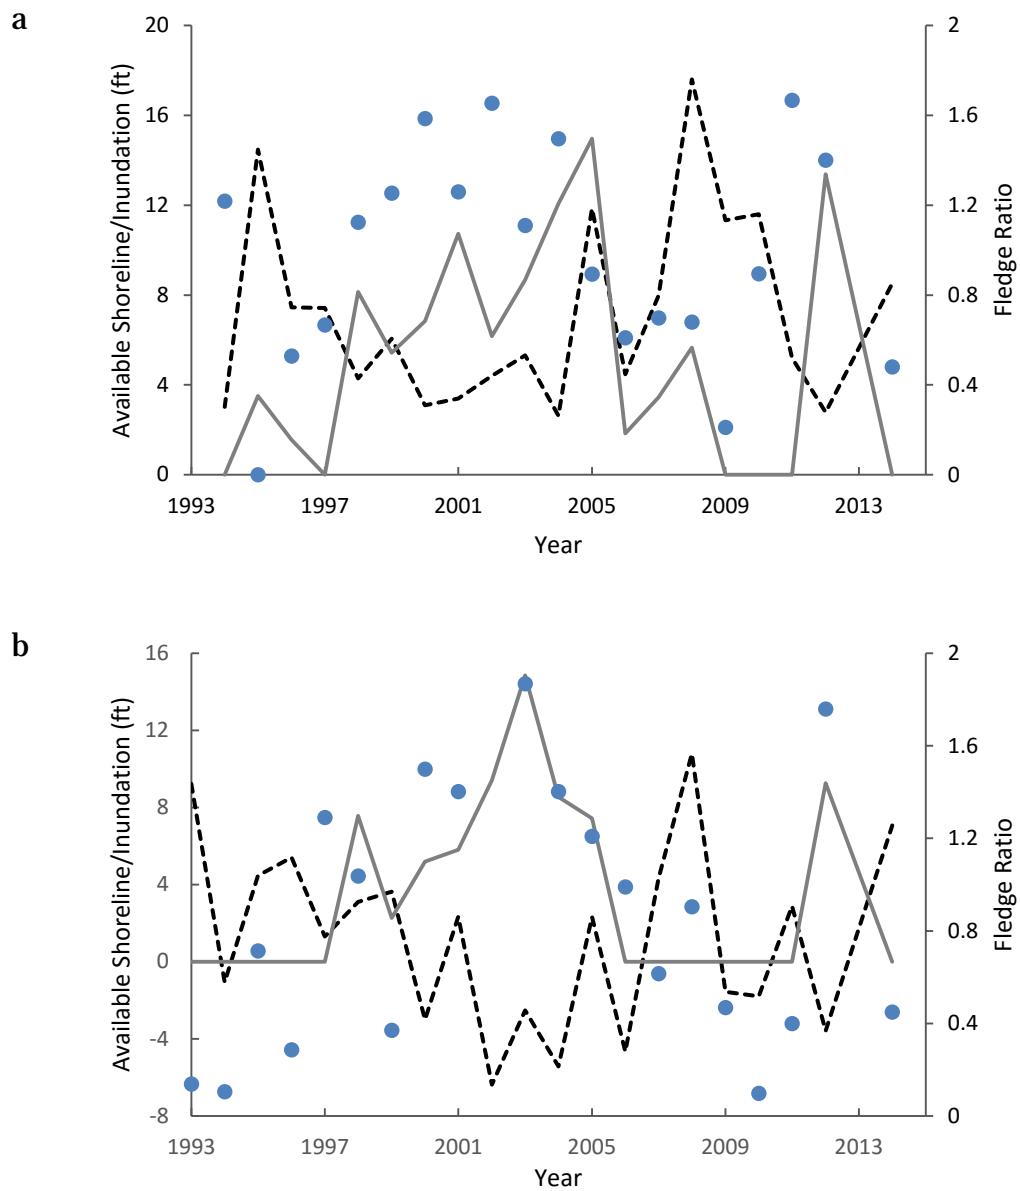

3 Figure 47. Observed standardized ESH (blue line) from 2006-2014 relative to targets (median, solid black line;
4 95% confidence interval, dashed lines) for a) the Northern region and b) the Southern region. Green circles
5 indicate years that the time frame of 3 out of 4 years exceeding the median target is met.

6

7

1 Figure 48. Observed exceedance of available ESH (blue) from 2006-2015 relative to target exceedance
2 distributions (median, solid black line; 95% confidence interval, dashed lines) for a) the Northern region and b)
3 the Southern region. Circles indicate the 75%, 50%, 25% and 10% exceedance criteria specified in the targets.
4 Note that only 10 years of data are available; a 12-year rolling window of data will be used once 12 years of
5 data are available. The observed exceedance meets the median targets for habitat availability if the blue line is
6 to the right of the solid black line.

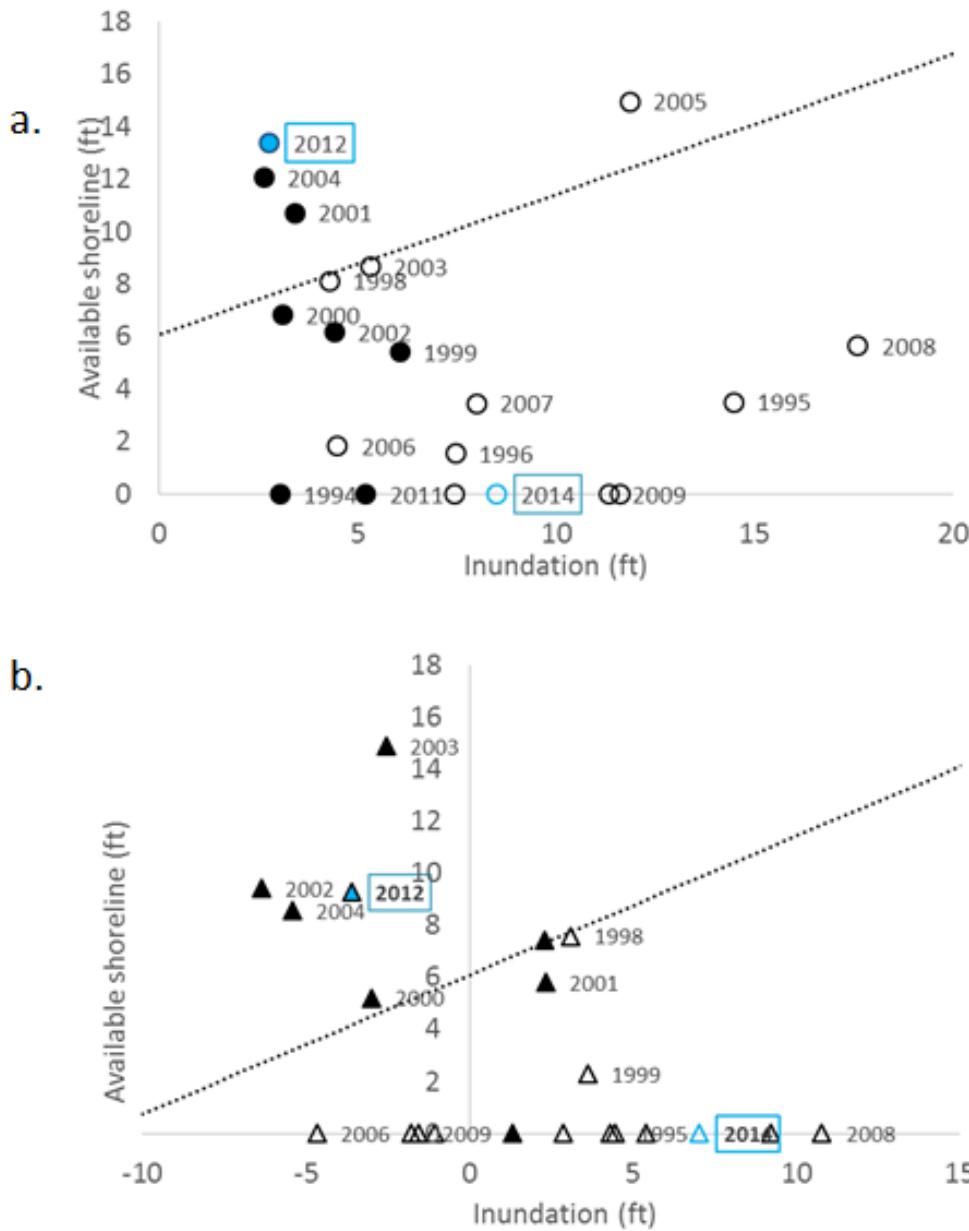

1 Figure 49. Metrics of available shoreline (solid gray lines, high values are good), inundation during the nesting
 2 season (dashed black line, low values are good) and observed fledge ratios (blue circles) for a) Lake
 3 Sakakawea and b) Lake Oahe. Fledge ratios on reservoirs were not estimated in 2013.

4 While there are no targets set for reservoir habitat, tracking the associated metrics is
 5 useful for understanding bird population dynamics on reservoirs and how they are
 6 affected by management decisions. Figure 49 shows reservoir habitat metrics by year for
 7 1993-2014 for each reservoir, with observed plover fledge ratios. Observed fledge ratios
 8 tend to be higher for high values of the available shoreline metric and low values of the
 9 inundation metric. Figure 50 shows the relationship between reservoir shoreline habitat
 10 metrics and whether or not plover fledge ratios meet their target. Patterns in reservoir
 11 shoreline water elevations and resulting fledgling production vary between the two

1 reservoirs, as Lake Sakakawea is more affected by inundation during the nesting season
 2 and Lake Oahe by changes in water elevation between years.

3

4

5 Figure 50. The relationship between reservoir habitat metrics (available shoreline and inundation) and whether
 6 the fledge ratio target of 1.14 is met (filled shapes) or not met (unfilled shapes) for a) Lake Sakakawea and b)
 7 Lake Oahe for 1993-2014. Recent years are highlighted in blue (fledge ratios were not estimated on reservoirs
 8 in 2013). Note that some labels have been omitted for legibility. The dotted line indicates combinations of the
 9 two metrics predicted by the model to meet the fledge ratio targets; data points above and to the left of the
 10 line are expected to meet the targets and data points below and to the right of the line are not.

1 **3.5.2 Evaluation of population status relative to targets and objectives**

2 The population sub-objectives for birds require that the MRRP 1) maintain the
3 geographic distribution of plovers, 2) maintain a resilient population, 3) maintain
4 population growth that is at least stable, and 4) maintain the success of breeding pair
5 levels that support population growth. Rather than a quantitative target of a number of
6 adults, criteria were set for long-term population persistence (low quasi-extinction risk).
7 Persistence is supported by population growth rates that are at least stable over time
8 and fledge ratios that allow the population to be at least stable, given current survival
9 estimates. Therefore assessment of population status requires assessment of observed
10 fledgling production, trends in population size over time and assessment of population
11 resiliency under current and proposed management conditions through modeling.

12 **3.5.2.1 Evaluation of fledge ratio and population growth rate**

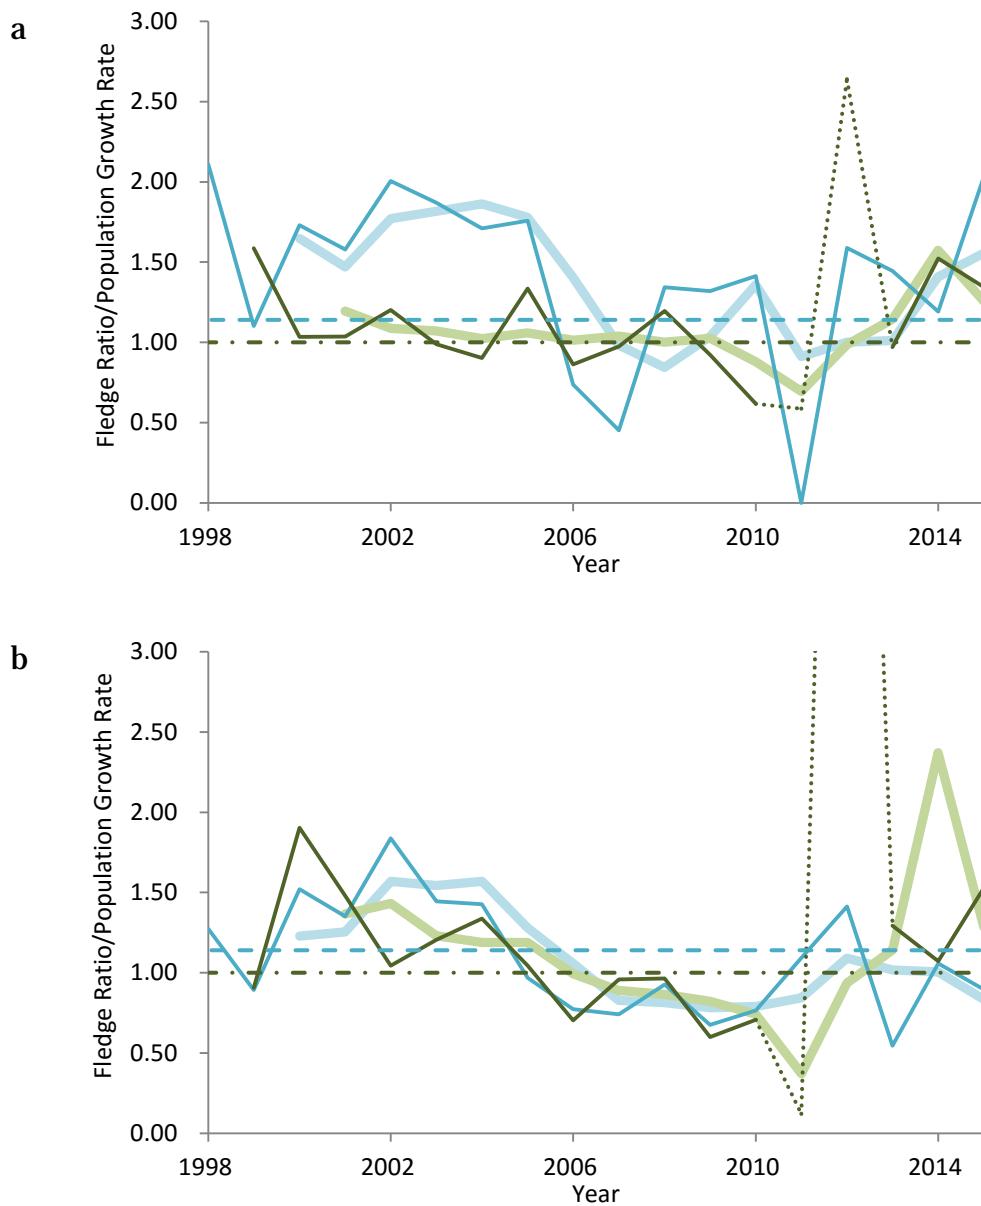

13 It is most straightforward to evaluate sub-objectives 3 (growth rate) and 4 (fledge ratio)
14 by directly comparing observed rates and running averages with targets (Figure 51).
15 Adjustments may be required to account for variability in estimated observation error,
16 in order to compare population sizes from year to year to calculate growth rate.
17 Adjustments may also be required to account for differential detection of adults and
18 fledglings to more accurately calculate fledge ratios.

19 Inter-annual variability in population sizes, growth rates, and fledge ratios is to be
20 expected in any population, particularly birds nesting in naturally variable habitat. In
21 some cases, a single-year deviation from meeting objectives is an early sign of a
22 downward trend that could result in jeopardy, while in others it represents natural
23 variability in an otherwise stable or growing population. Assessment of species status
24 needs to be able to recognize early signs of population decline while not causing
25 overreaction to natural variability. Thus assessment of species status include assessment
26 of the most recent year but also a measure of the metric over a 3-year running geometric
27 mean (for population growth rate) or arithmetic mean (for fledge ratio). These metrics
28 should be interpreted in the context of overall habitat and species status and trends,
29 scientific understanding, and ancillary information.

30 **3.5.2.2 Evaluation of population trajectory and resilience**

31 Population resiliency can be assessed through model projections over a 50-year time
32 frame, based on current conditions and management practices, to estimate whether the
33 population under the specified conditions is expected to meet the persistence criteria
34 (remain above the quasi-extinction threshold of 50 adults in each region in more than
35 95% of model replicates). It is challenging, however, to realistically project current
36 management conditions over a 50-year time frame, and such assumptions of

- 1 management consistency do not reflect ongoing AM that would be expected to improve
 2 management outcomes over time.

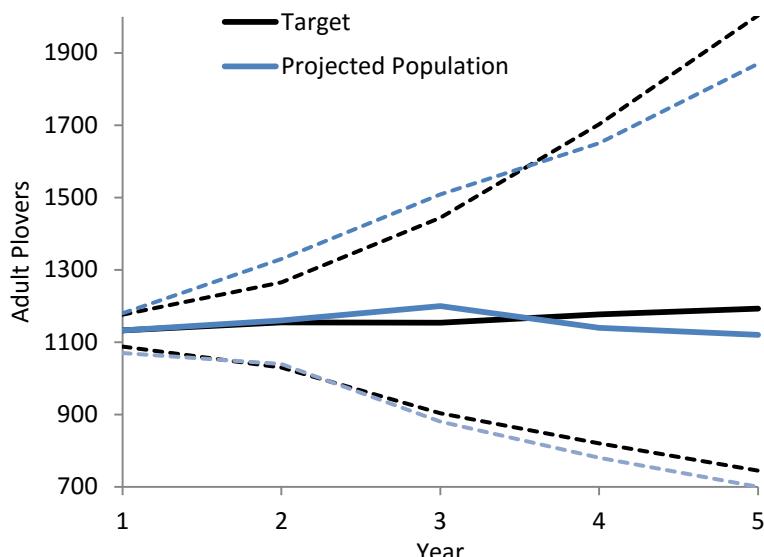

3 Figure 51. Plover population growth rate ($\lambda = N_t/N_{t-1}$) (green) and fledge ratio (blue) annual values (thin lines),
 4 3-year running geometric mean of growth rate (thick green line) and 3-year running average fledge ratio (thick
 5 blue line) from population monitoring 1998-2015 for a) the Northern Region and b) the Southern Region.
 6 Years with especially low and high population growth rate (2011-2012; dotted lines) reflect the effect of high
 7 flows that did not allow breeding in 2011. As few nesting birds were observed in 2011, calculated population
 8 growth reflects the absence then return of birds to nesting areas in addition to changes in population size due
 9 to reproduction and mortality. Dashed lines indicate targets.

10 An alternative is to model a scenario in which the persistence criteria are just met, and
 11 evaluate the current and near-future (5-10 year) population status against those

1 projections. The greater the overlap between the target and projected future population
2 distributions, the greater the likelihood that targets will be met without “over managing”
3 the system. For example, population projections beginning in Year 1, with enough
4 habitat availability to meet ESH targets, provide a distribution of population sizes that
5 should be met in the next five years in order to be on track for long-term viability (e.g.
6 Figure 52). This approach acknowledges that population trajectories are more important
7 than single-year population status (e.g. a small, but growing, population with abundant
8 habitat is more likely to persist than a larger population with limited habitat in the long
9 run) and that there are time lags in population response to changes in available habitat.

10 While an absolute population target cannot be defined for all circumstances, a target
11 population trajectory for the next 5-10 years, given current circumstances, *can* be
12 defined. The degree of overlap between the target population distribution and the
13 distribution expected from planned management actions can be quantified to assess the
14 likelihood of success. For example, an overlap of 85% between the target distribution
15 and the management scenario distribution would be preferable to an overlap of only
16 50%. If the management scenario distribution is lower than the target distribution, it is
17 unlikely that the habitat and population targets will be met. If the management scenario
18 distribution is greater than the target, there is increased likelihood that the targets will
19 be met, but also that more resources will be used than are strictly necessary.

20

21

22 Figure 52. Hypothetical comparison of projected population sizes under a management scenario (blue lines)
23 with a population trajectory that meets the target (black line). Solid lines are median values of 5,000 model
24 replicates; dashed lines are 95% confidence intervals.

1 3.5.2.3 Accounting for metapopulation and non-breeding habitat dynamics

2 The Missouri River tern and plovers populations are not closed; birds born or previously
3 breeding in other areas may immigrate to breed on the Missouri River, and vice versa.
4 All plovers and terns breeding on the MRMS winter elsewhere. Conditions during
5 migration and at wintering and other breeding habitats affect individual bird condition,
6 annual survival and dispersal, and thus affect MRMS population dynamics. It is
7 important to distinguish these effects from effects of MRMS management actions.

8 By examining the status and trends of both fledge ratios and population size and growth
9 rates, and incorporating ancillary information (e.g. knowledge of conditions and
10 demographics in other habitats), growth rates that are not in pace with fledge ratios—
11 suggesting changes in survival or dispersal—can be identified and, if possible, attributed
12 to changes on or off the Missouri River. Explanations for discrepancies can be taken into
13 account for management planning. Long-term changes off-river affecting Missouri River
14 populations may require adjustments to target criteria or objectives at the
15 policy/Oversight level. Future metapopulation modeling will incorporate this
16 information as it becomes available in order to improve management decisions.

17 **3.5.3 Overall Evaluation of Status and Management Needs**

18 A holistic assessment of the status and trends of bird populations relative to habitat is
19 half of the foundation for decisions regarding whether actions should be implemented,
20 where, and with what intensity (Figure 40). ESH targets provide guidelines for a
21 resilient population in the long term; the needs of the population in a given year depend
22 on population size relative to habitat availability (population density) and population
23 trends.

24 A matrix summarizing the status and needs of plovers and ESH (Table 35) provides a
25 heuristic for assessing and communicating the current habitat and species status and
26 recommended overall pathway of management (e.g. continue, increase, or decrease
27 current rates of habitat creation; corresponding rates of habitat maintenance may also
28 be indicated) resulting from that status. To meet objectives, populations must be
29 growing or stable (first two rows of table) and above the lower bound of the ESH targets
30 (second through fourth columns). Outside of that range the population may be on track
31 to meet objectives, unlikely to meet objectives, or potentially in reversal (was meeting
32 objectives but no longer is).

33

34

Population Status	Emergent Sandbar Habitat Status			
	Acreage < Lower Bound	Lower Bound < Acreage < Median	Median < Acreage < Upper Bound	Upper Bound < Acreage
GROWING POPULATION FR and λ > target	On track to meet objectives Status: Small population OR density dependence less than expected Need: Continue pace of habitat creation	Meeting objectives Status: Moderate population, not habitat limited Need: Continue habitat creation at current or slower pace	Meeting objectives Status: Moderate to large population, not habitat limited Need: Maintain existing acreage and quality	Exceeding objectives Status: More birds and much more habitat than needed Need: Maintain habitat quality
STABLE POPULATION FR and λ ≈ target	Unlikely to meet objectives Status: Small to moderate population, becoming habitat limited Need: Increase rate of habitat creation	Meeting objectives Status: Moderate population, habitat may become limiting Need: Continue pace of habitat creation	Meeting objectives Status: Moderate to large population Need: Maintain existing acreage and quality	Exceeding objectives Status: More birds and more habitat than needed Need: Maintain habitat quality
DECLINING POPULATION FR and λ < target	Will not meet objectives Status: Small to large population, very habitat limited Need: Rapidly increase rate of habitat creation	Unlikely to meet objectives Status: Moderate to large population, habitat limited Need: Increase pace of habitat creation	Potential reversal Status: Large population returning towards equilibrium Need: Continue pace of habitat creation and maintain habitat	Reversal Status: Large population returning towards equilibrium OR density dependence much higher than expected Need: Maintain habitat quality, consider maintaining acreage

1

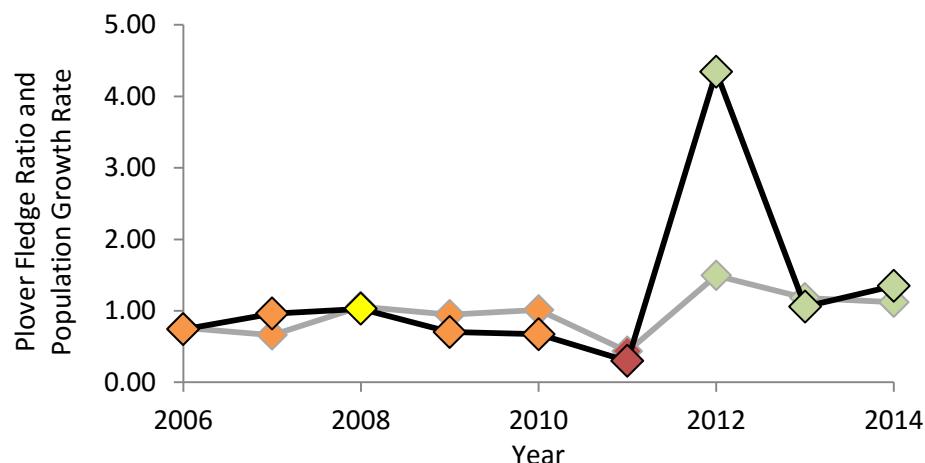

2 **Table 35. Status-and-needs matrix for ESH and birds.** The population status and habitat action needs depend
 3 on whether the population is growing, stable, or declining based on growth rate (λ) and fledge ratio (FR) and the
 4 ESH acreage relative to targets. Bold text indicates the status relative to the targets. The cell color summarizes
 5 the status and needs: dark green = objectives are being met and current management (habitat creation rates)
 6 should continue; light green = management objectives are exceeded and management can be reduced; yellow
 7 = species may be on or near the path to meet objectives, but management increases may be necessary;
 8 orange = objectives are not being met and unlikely to be met and management must increase; red = objectives
 9 will definitely not be met and strong increases in management must occur.

1 The status-and-needs matrix makes several important assumptions for simplification:

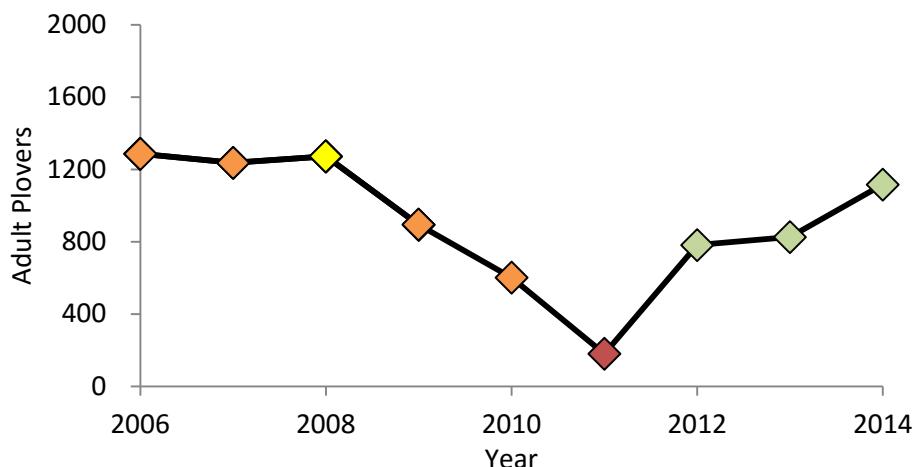

- 2 • Plover populations grow or decline based on population density (the number of
3 adults/acre), according to the best available science about density dependence in
4 plover populations. That is, growing populations are at low densities (first row of
5 matrix), declining populations are at high densities (third row) and stable
6 populations (second row) are at moderate, equilibrium densities. ESH acreage
7 targets are built upon those assumptions. If density dependence is substantially
8 different than that estimated when calculating ESH targets, unexpected outcomes
9 may occur. This possibility is noted twice in the matrix: a population growing when
10 ESH is less than the lower bound of the habitat targets is either quite small (low
11 density) or the population can grow at higher densities than expected. Similarly, a
12 population declining when ESH is above the upper bound of target acreage is either
13 very large (high density) or density dependence is higher than expected. Such
14 possibilities may occur within other cells in the matrix as well. When evaluating
15 status, a check of recently observed productivity related to density should be made to
16 ensure population dynamics are within the bounds of this assumption. If there is a
17 deviation over multiple years, then management decisions need to account for a
18 possible bias and ESH targets may need to be re-evaluated.
- 19 • The relationship between growth rate (λ) and fledge ratio (FR) is roughly consistent
20 over time. This is only true as long as survival and emigration/immigration are also
21 consistent over time (annual variability is expected, but the distribution of rates is
22 expected to be stationary). If overwinter survival declines, emigration increases, or
23 immigration increases, the calculated equilibrium fledge ratio may not support
24 equilibrium population growth. The reverse is also true. If such variations occur, the
25 population status would not fit in a single row of the matrix. In those cases, fledge
26 ratio should determine where the status of the species lies, as that is most directly
27 affected by MR management actions (i.e. management actions primarily address
28 reproductive success, and cannot address conditions of overwinter habitat, which
29 affect survival, or conditions in other breeding areas, which affect dispersal).
- 30 • Growth rate and fledge ratios are generally in sync. In reality, there is usually a time
31 lag for changes in fledge ratio to be reflected in changes in population size,
32 particularly when reversals occur. A declining population that has begun to grow
33 again may have fledge ratios above equilibrium but growth rates below equilibrium
34 for a year or two until the increase in fledglings is reflected in the population size.
35 The same is true for growing populations that begin to decline.
- 36 See Section 3.5.11 (unexpected outcomes) for more discussion of handling observations
37 that fall outside habitat or population dynamics as they are currently understood.

1 As long as the simplifying assumptions are taken into account, the status-and-needs
 2 matrix provides a shortcut for determining which path of action should be taken with a
 3 holistic understanding of both habitat and species status and trends. It also can be used
 4 to summarize and illustrate species status over time (Figure 53). Use of the matrix does
 5 not replace more detailed technical analysis and interpretation of habitat and
 6 population trends and forecasts. Quantitative modeling and assessment determines how
 7 much management and which action should take place. At a minimum, the acreage
 8 required to achieve or maintain habitat goals with a desired level of confidence is
 9 needed prior to making decisions. Tables generated from the ESH models simplify this
 10 process (see Fischennich et al 2016). If targets are not being met, the process and
 11 decision criteria to ensure shortfalls are corrected are described in Section 3.6.5.

12

13

14

15 Figure 53. Evaluation of status over time for a) plover fledge ratio (gray lines) and population growth rate (black
 16 lines) and b) plover population size. Symbol color indicates status relative to status and needs matrix (see
 17 Table 346 for definitions.)

1 3.5.4 Evaluation of management conditions

2 The evaluation of management conditions is the other half of the foundation for
 3 decisions, providing the necessary information on what actions are possible.
 4 Management conditions define the constraints on actions in a given year (Table 36).
 5 Management conditions of standardized acres, vegetated habitat, and population
 6 density determine whether habitat creation, vegetation removal, and predator control,
 7 respectively, would be effective and how much benefit would likely be gained (Section
 8 3.2.2.3). Information on storage and tributary flows determines whether flow
 9 modification actions are feasible, their expected effectiveness, and opportunity for ESH
 10 construction or maintenance. Budget and logistics determine the capacity for most non-
 11 flow actions. Constraints related to storage, flows, and budget must be determined in
 12 the context of the entire program including operation for authorized purposes, pallid
 13 sturgeon management actions, research, and other costs.

14 Table 36. Summary of management condition constraints and opportunities relative to management actions.

Management Condition	Standard ESH acres	Vegetated sandbar acres	Storage	Planned releases	Tributary flows and downstream stage	Bird population density
Management Action	In Preferred Alternative					
Mechanical construction	Amount of construction based upon current status relative to targets	High vegetated acreage may restrict suitable area for new bars	Increasing storage increases need for river habitat in north	Can only build if cfs < 35,000		Higher priority for building when density is higher
Sandbar augmentation and modification	Limited by extent and condition of available ESH	Sandbars with late successional vegetation less suitable for modification		Can only build if cfs < 35,000; can only modify what is above current flows		Use when bird density is moderate to high
Flows to avoid take				Releases set in May to accommodate downstream needs and forecasts	Accommodate downstream flood risks with lower releases; increases afterwards increase inundation risk	
Vegetation management		Limited to extent of vegetated acres		Only possible if stage is lower than vegetated habitat		

Predation management	May not be practical if acreage high	Vegetation increases need for predation management				Use when density $>\sim X$
Human restrictions						
Not in Preferred Alternative						
Habitat-creating flow	Most effective when combined acreage $< X$	Storage > 42 for spring release; > 35 SL for fall release	TBD	Flow less than 71 kcfs at Omaha, 82 kcfs at Nebraska City, or 126 kcfs at Kansas City	Most needed when density is moderate to high	
Lowered nesting season flow	Moderate acreage ($X < \text{acreage} < Y$)		If water must be evacuated, low flows are unlikely (storage $> ??$)	Low flows more likely when below full service (specifics)	Accommodate water supply and navigation needs	Use at moderate to high population densities

1

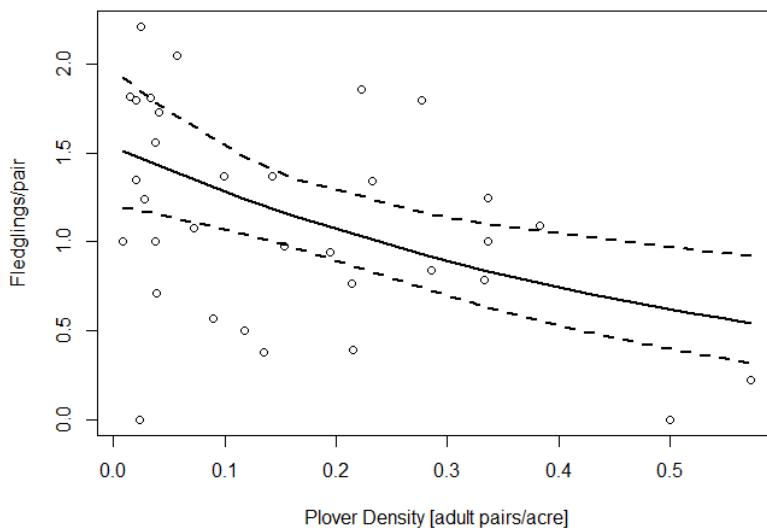

2 3.5.5 Incorporation of new information

- 3 Research that is conducted over the course of the year is summarized in the annual AM
 4 report. MRRP-funded research will typically be reported upon in the Fall Science
 5 Meeting and the Annual AM workshop. Relevant non-MRRP research findings will also
 6 be discussed in the report when available, with consideration given to the level of
 7 QA/QC and peer-review or related evaluations such findings have undergone and to the
 8 design and strength of studies (For example, a study conducted over a single year with a
 9 small sample size would generally not be given as much weight as a multi-year study
 10 with larger sample sizes, particularly if the results of the studies are contradictory. For
 11 an example of a weight-of-evidence approach, see Diefenderfer et al. 2016.)
- 12 Occasionally, new or unexpected information might become available that has the
 13 potential to significantly alter some aspect of management under the MRRP and which
 14 is not captured in the annual AM science process. This may be a matter of timing
 15 (urgent findings which miss the AM reporting cycle) or because the information was not
 16 identified by the Technical or Bird Teams. Such information would be vetted and
 17 addressed through the process described in Section 6.2.5. Important insights emanating
 18 from the vetting process would be incorporated into the AM process in the same way as
 19 other monitoring and assessment results.

1 **3.5.6 Evaluation of key relationships and science questions**

2 Beyond determining system status, monitoring and research provides information for
 3 evaluating the critical uncertainties and management hypotheses (Section 3.1.2.5, Table
 4 19). The assessment of evidence for hypotheses should be revisited annually to
 5 incorporate any new findings. The level of support for management hypotheses, as
 6 evaluated by the Technical Team should then be considered by the Bird Team when
 7 determining priorities for WP updates.

8 In addition to the critical uncertainties and management hypotheses, the physical and
 9 biological relationships underlying the conceptual and numerical models should be
 10 evaluated regularly. For example, the hypothesis that plover fledgling production is a
 11 function of habitat availability and population density underlies the model predictions,
 12 objectives and targets, and is the focus of the majority of management actions. New
 13 monitoring data collected each year adds information for routine analyses, following the
 14 EA (Buenau et al. 2014); e.g. Figure 54, and indicates where in the estimated density-
 15 productivity function the system currently falls. Updated analyses are reported annually
 16 and results are applied to ongoing modeling (see Section 3.5.7). Most analyses can be
 17 done quickly and consistently across years using established scripts in statistical
 18 software (e.g. R), though these approaches should be evaluated periodically and may
 19 need adjustments if monitoring protocols change.

20 Figure 54. Example of an evaluation of key relationships. Results of best-fit model relating plover density to
 21 fledge ratio in annual assessment of density dependence in plover population. Points indicate fledge ratios in
 22 individual reaches and years, solid line is median prediction of model, dashed lines are 95% confidence
 23 intervals.

24 For questions that can be addressed quantitatively, the degree of uncertainty can be
 25 quantified and used to track the learning process as new information is added. New

1 understanding may allow questions to be refined, or answered conclusively enough that
2 they need no longer be evaluated as frequently. The potential for long-term change in
3 system drivers suggests that hypotheses should be confirmed or re-confirmed over
4 longer time periods. Additional science questions and management hypotheses may also
5 be identified if new situations arise.

6 **3.5.7 Evaluation of action effectiveness**

7 The effects of management actions, particularly those with high uncertainty, can be
8 assessed by predicting outcomes, monitoring the effects of action implementation, and
9 then evaluating predicted vs. observed effects. An example of evaluating a habitat
10 forming flow test is below.

11 **Pre-implementation assessment:** Decisions regarding implementation of habitat-
12 forming flows will be based on application of the ESH models to: 1) forecast the outcome
13 of each of several potential releases (e.g. lower magnitude/longer duration vs. higher
14 magnitude/shorter duration) given the ambient ESH acreage, resulting in an expected
15 value and distribution of ESH created, along with likelihood that target acreage will be
16 reached or surpassed, and 2) assess the value of information from potential releases
17 based on uncertainty assessment. Hydrological models and forecasts of flows, including
18 the range of flows evaluated in the AOP, are used to 1) calculate a likelihood that the
19 flow releases would have to be terminated early due to downstream conditions, and if
20 so, the range of actual implemented flows that would result, and 2) assess relevant HC
21 metrics across range of potential releases, with distribution of expected outcomes of
22 impact or benefit and risk of exceeding critical thresholds. These assessments should
23 include any of the relevant new decision rules (not used in the EIS evaluation) outlined
24 in Section 5.8. Relevant models would also be run to assess synergistic or detrimental
25 impacts of flow action on pallid sturgeon.

26 Potential benefits of a creation flow would be weighed against risks and discussed
27 during the Work Plan engagement process (Section 2.4.4). Relevant risks include the
28 likelihood and severity of HC impacts (individually and/or cumulatively) and the
29 likelihood of early termination due to downstream flood constraints. A number of
30 structured processes for decision making exist (see Section 2.4.5.2), and one or more of
31 these processes would be employed to support the necessary decision. In time, the
32 nature of the uncertainties may decline and/or risk tolerance may rise to the point that
33 other decision rubrics may apply. For example, projected outcomes could be converted
34 to indices and weighted towards overall assessment: <e.g. ESH created * likelihood of
35 full implementation + value of information + synergistic benefits (including HC
36 benefits)/sum of HC impacts>. A ratio in excess of some threshold (e.g. 3.0) may be
37 required in order to proceed with the flow action.

1 **Monitoring, after-action assessment and reporting:** Monitoring of actual flow
2 and HC outcomes would typically occur before, during and following implementation,
3 depending on the specific issues being monitored (see Section 5.5.5). Monitoring of
4 standardized ESH acreage is made on an annual basis in June and July, except for more
5 detailed studies of ESH in sub-reaches. After-action assessment and reporting includes:

- 6 • A comparison of observed and projected hydrology at decision-relevant gages, with
7 an explanation of any observed deviation and its relevance.
- 8 • A comparison of observed and projected HC impacts at decision-relevant locations.
9 If there are deviations, can they be explained by deviations from expected hydrology?
10 If not, are there errors/uncertainty in the HC models that should/can be addressed?
11 (Models should be rerun with observed hydrology to distinguish between causes of
12 error.)
- 13 • A comparison of observed and projected ESH outcomes for the reach and at any
14 decision-relevant locations. If there are deviations, can they be explained by
15 deviations from expected hydrology and/or normal range of variability? If not, are
16 there errors/uncertainty in the ESH models that should/can be addressed? (Models
17 should be rerun with observed hydrology to distinguish between causes of error.)
- 18 • Depending on the results of the above steps, outcomes either support existing
19 models (dynamics occurred well within expectations, quantifiable to a Z-score) or
20 provide information for challenging/updating models and other information. For
21 ESH models, monitoring protocols should provide information that is always used
22 through a protocol of verifying/updating the ESH models. Such procedures may also
23 be developed for HC or sturgeon models as appropriate.
- 24 • Learning outcomes are quantified through estimates of reduction of uncertainty.

25 **3.5.8 Evaluation of cross-program effects**

26 Any observed effects of pallid sturgeon actions on birds, positive or negative, will be
27 noted in the Science Update process. The anticipated effects of pallid sturgeon actions
28 on birds (Table 31) are hypotheses that can be evaluated like the management
29 hypotheses for bird actions. Biologically significant effects that increase or reduce the
30 likelihood of meeting demographic or ESH targets may indicate that programmatic
31 decision criteria and/or tradeoff assessments (see Section 2.2.2) should be reviewed to
32 ensure they reflect new understanding of synergistic or negative interactions.

33 Similarly, effects of reservoir operations or other activities not specifically tied to bird or
34 pallid sturgeon management should be noted and evaluated as part of the ongoing EA.

1 **3.5.9 Model updates and validation**

2 A primary mechanism for capturing and applying learning is incorporating new
3 information collected during the previous year, if appropriate, into the models. This
4 includes a) assessments based on monitoring data updated on an annual basis (e.g.
5 habitat-productivity analyses, Section 3.5.6), b) information from research studies or
6 short-term additional monitoring (e.g. geomorphic assessments following flow events)
7 and c) information from external studies deemed to be of sufficient quality and
8 relevance.

9 Routine updates of ongoing assessments based on monitoring data are straightforward.
10 New data follows the same format and can generally use the same processing
11 procedures, statistical methods and code. These assessments should be evaluated
12 periodically to ensure they reflect up-to-date understanding and methodologies.
13 Changes to the monitoring program or data management system may require some
14 updates to procedures or analytical scripts. Incorporation of information from different
15 studies or collected with new methodologies is more challenging. Case-by-case decisions
16 must be made regarding whether new information should replace or be combined with
17 previous information.

18 Updating model parameters with new information is straightforward to implement and
19 is documented in the annual report, with annual modeling reflecting new information.
20 These evaluations will be conducted by the Technical Team, but the Technical Team
21 may consult with the Bird Team and/or Management Team about the use of additional
22 information and should report on the effects of the changes being made as relevant to
23 decision-making.

24 New information may allow for structural changes to the models (e.g. modeling ESH at
25 finer scales), requiring additional time to develop, code, and test changes. In such cases,
26 comparison of old and new model results (using otherwise the same parameters) should
27 also be reported, to provide understanding of the consequences of the changes to model
28 structure and function and the decisions informed by modeling.

29 Model validation procedures test model accuracy and precision by comparing model
30 predictions with observations that were not used to parameterize the model. For
31 example, adult counts were used to predict fledglings/pair/acre relationships for the
32 plover model but not to predict population growth rates themselves within the model.
33 Predicted and observed population growth rates can be compared as a form of model
34 validation. Multiple levels of validation are useful for assessing model accuracy and
35 identifying where error occurs:

- 1 • Comparison of observed and predicted standardized and available ESH, using actual
- 2 flows (tests ESH model accuracy)
- 3 • Comparison of observed and predicted standardized and available ESH, using
- 4 modeled flows (tests ability to predict future ESH dynamics, when flows are
- 5 unknown, given model accuracy and distributions of modeled flows)
- 6 • Comparison of observed and predicted fledge ratios and population sizes, using
- 7 observed ESH (tests accuracy of population models alone)
- 8 • Comparison of observed and predicted fledge ratios and population sizes, using
- 9 predicted ESH (tests overall ability of model suite to predict population dynamics)

10 An example of model validation for the 2nd and 4th types of comparison, using data from
11 2005 to 2014, is shown in Figure 55. Model accuracy will vary depending on the time
12 frame used; consistent time frames (e.g. 5 years) should be used for reporting and
13 should be decision-relevant.

14 Models are statistically validated by comparing projected (model results) and observed
15 (monitoring data) values for several parameters based on standard deviation scores (*z*;
16 Tyre et al. 2000; Sheskin 2007), such that

$$17 \quad z = \frac{X - \mu}{\sigma},$$

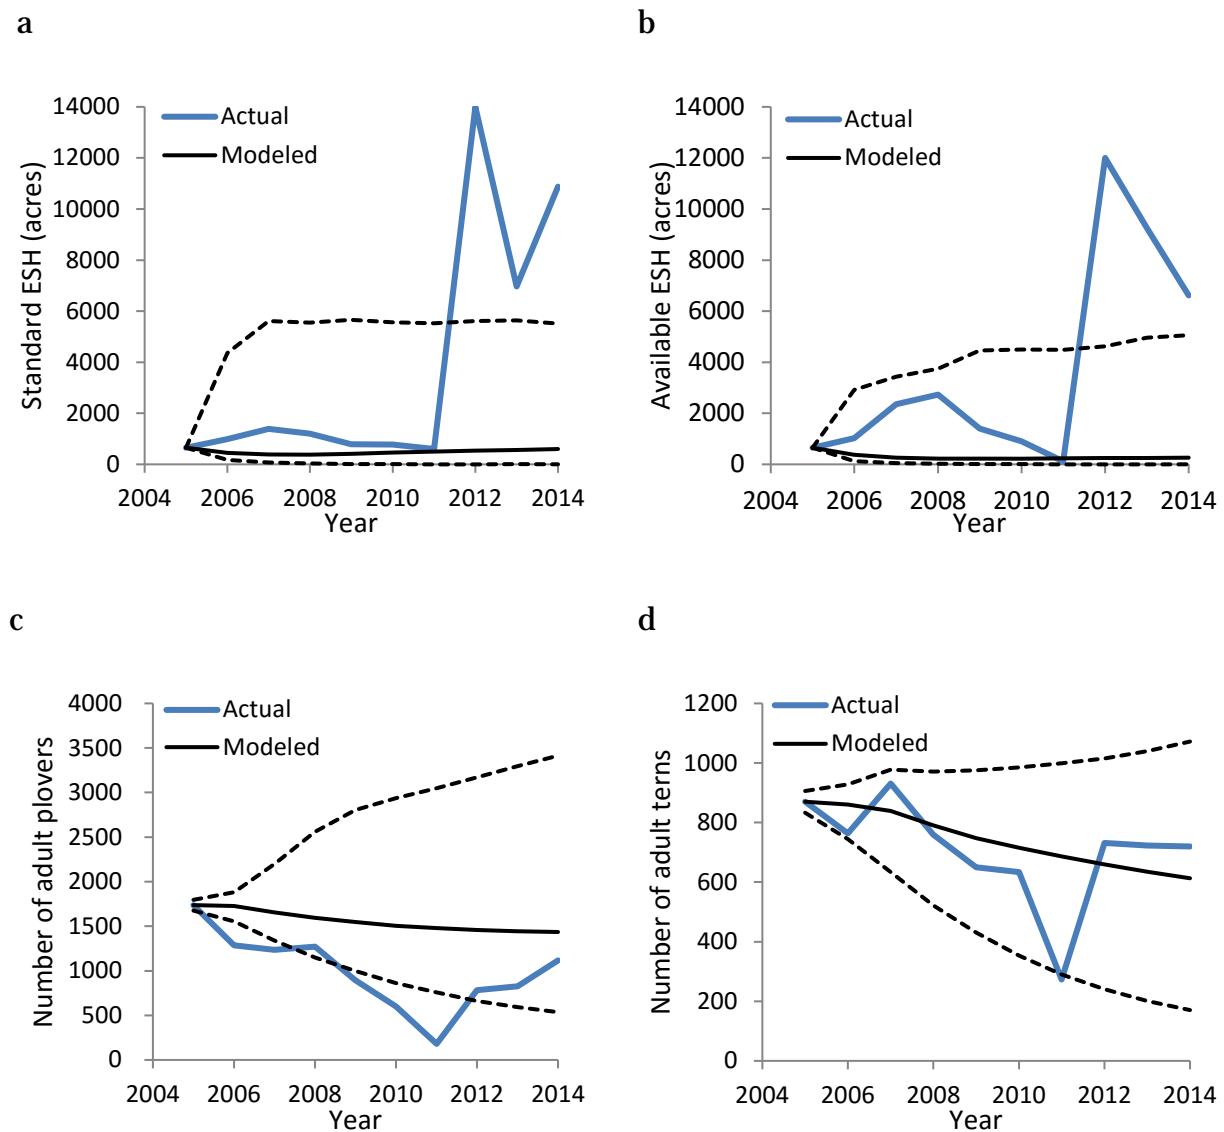

18 where *X* = observed value (e.g., population size estimate from monitoring data), μ =
19 projected value (e.g., average projected population size estimate), and σ = standard
20 deviation (e.g., standard deviation of model projected population sizes). This score is a
21 measure of distance from the mean in standard deviation units, and is normally
22 distributed with mean = 0 and variance = 1. The more similarity between projected and
23 observed values, the closer the *z*-score is to zero, resulting in more evidence that model
24 results are accurate. If the model is overprojecting the observations, then the *z*-scores
25 will be negative. If the model is underprojecting the observations, then the *z*-scores will
26 be positive. Statistical significance of *z*-scores is then tested using *P*-values, assuming
27 that model results and monitoring or habitat data differed if $0.05 > P > 0.95$.

28

29

30

31

1 Figure 55. Example of model validation for 2005-2013 for a) standard ESH and b) available ESH modeled
 2 using predicted flows (validation type 2 above) and c) plover adults and d) tern adults using predicted ESH
 3 (validation type 4 above). Solid black lines indicate the median prediction of 5,000 model replicates; dashed
 4 black lines indicate the 95% confidence interval. Thick blue lines are observations.

5 3.5.10 Ancillary information

6 Additional information that is qualitative or site-specific also reflects learning and
 7 should be captured and synthesized. Examples of ancillary information include:
 8 observations about habitat quality on individual sandbars that could be addressed with
 9 management actions; local events such as storms that negatively impact bird survival
 10 and overall performance; observations of birds nesting in unusual locations; or patterns
 11 of ESH erosion. Such information should be quantified and systematically reported
 12 along with monitoring data in annual reports. Other information sources can be
 13 included if appropriately vetted (see section 6.2.5). Such information can be used to

1 adapt local management actions, help explain patterns in monitoring data (e.g. multiple
2 local factors could result in unusually high or low productivity in a reach), and identify
3 questions and hypotheses for future research and analyses. The quality of ancillary
4 information will vary and may be subject to bias due to how factors are observed (e.g. a
5 lack of observations during bad weather when fieldwork cannot be conducted) and
6 should be assessed when data is collected and/or compiled. Ancillary observations may
7 indicate the need for more systematic monitoring of factors not previously monitored.

8 **3.5.11 Unexpected outcomes**

9 Unexpected outcomes occur when observed habitat or population dynamics fall outside
10 of the range of behavior predicted by the models or otherwise anticipated from the
11 understanding of the system. Examples include: ESH eroding or depositing much more
12 or less than predicted given flows that occurred; bird populations continuing to grow
13 when habitat is limited and population density is high, or conversely populations that
14 are declining despite an excess of suitable habitat. Unexpected outcomes have three
15 possible explanations:

- 16 6. Error in mechanisms of the models and/or foundational hypotheses: key driving
17 factors are not represented, or represented in a functionally incorrect way that
18 cannot predict observed dynamics.
- 19 7. Error in parameterization of models: the models have the correct mechanisms, but
20 were parameterized in ways that cannot predict observed dynamics—i.e. the
21 parameters are wrong or do not adequately cover the range of potential inputs.
- 22 8. A combination of mechanistic and parameterization error.

23 These errors have several possible sources:

- 24 • Insufficient or poor quality data were available for testing hypotheses and
25 parameterizing models;
- 26 • Data were analyzed incorrectly;
- 27 • Fundamental processes have changed and older data used to test hypotheses and
28 parameterize models no longer reflect conditions (e.g. climate-driven changes in
29 hydrology; long-term changes to sediment budget; changes to bird survival because
30 of migration or winter conditions, or disease, or other factors not captured in the
31 models);
- 32 • Some combination of 1-3.

33 No model is completely accurate. Models used in this AM process explicitly incorporate
34 and project uncertainty. Minor to moderate deviations of observations from projected
35 outcomes are expected—adherence of real populations to median population projections
36 would be highly unlikely. The degree of deviation, as calculated through the model

1 validation process, and the direction of error are of more concern. Large deviations, and
2 those consistently higher or lower (biased), should trigger assessments of why such
3 error occurs.

4 If an explanation for error cannot be found or corrected, consistent biases in model
5 projections should be identified so that management decisions can respond accordingly.
6 For example, if population projections are biased high compared to observations, more
7 conservative actions (i.e. higher rates of habitat construction) should be considered to
8 compensate until models can be improved. Meanwhile, model validation and associated
9 analyses can be used to identify areas of critical uncertainty and potential error that
10 need to be addressed through research or enhanced monitoring.

316 Decisions and planning contingencies

12 Routine decisions for plover and tern management include when to act, how to act, how
13 much of an action to implement, and how to conduct research and monitoring. These
14 decisions must be made in a programmatic context, incorporating pallid sturgeon
15 management needs and human considerations. They are also made within the current
16 planning context: i.e., which actions are available for use under the ROD. This section
17 includes decisions which have been identified as part of the Preferred Alternative as well
18 as actions that have been evaluated but not included in the Preferred Alternative.
19 Decision criteria have been developed for both categories to represent the AM process
20 across alternatives evaluated in the MRRMP EIS.

21 The following sections, as well as the descriptions of actions in Section 0, provide
22 guidelines and decision triggers for management action implementation. Decision
23 criteria and triggers provide a pre-specified roadmap to follow and allow for general
24 estimation of the relatively likelihood of specific actions occurring in practice. However
25 it must be recognized that the Missouri River system is too complex and variable to pre-
26 specify every contingency in a way that would optimize the effectiveness and efficiency
27 of on-the-ground management. Predictive models aid in the evaluation and selection of
28 management options; their use in this context is described below. Models, too, cannot
29 account for all available information and situational constraints. Judgment and current
30 scientific understanding must be applied when using decision criteria and triggers.

31 As described in Sections 3.5.2 and 3.5.3, decision-making relies upon the identification
32 of management needs and management opportunities for the next 3-5 years. This
33 information determines the scope of decisions to be made.

1 **3.6.1 Decision making process**

2 The annual decision-making process is described in full in Section 0, with a brief
3 summary focused on bird management provided here. Following the evaluation phase
4 and the release of the Draft Annual AM Report, the Bird Team meets to develop a list of
5 priorities for updating the multi-year Work Plan. Activities for the current FY are
6 already set, and budget has been established for FY+1. The Bird Team may identify
7 adjustments to the plans for FY+1, but their focus is on specific planning for FY+2 and
8 general planning, including estimates of budget needs, for FY+3 and FY+4.

9 Using information provided from the Technical Team and guidance on program
10 direction, the Bird Team develops a ranked list of priorities. While aware of the
11 anticipated budget and competing uses of funding, water, and other resources, the Bird
12 Team focuses on identifying plover and tern management needs without attempting to
13 balance programmatic needs. In this way they can identify the optimal pathways to
14 meeting bird objectives, allowing the Management Team to make the decisions needed
15 to balance programmatic needs. The Bird Team would typically identify a suite of
16 actions, including more actions than may be required to meet the targets, and identify
17 any key dependencies among the actions, so that the Management Team can consider
18 alternative approaches when formulating the draft Work Plan. The Bird Team may also
19 identify more than one management option (i.e. alternative strategy); this is most likely
20 to occur when a flow action is proposed as an alternative to construction of ESH, as
21 tradeoffs will need to be considered and contingency plans identified in case the flow
22 cannot be implemented.

23 The Management Team uses the prioritized lists from the Bird, Fish and HC Teams to
24 allocate resources and identify which actions can be implemented, while taking budget
25 and HC factors into account. If flow modifications outside of routine operations are
26 being considered, the Management Team may make recommendations and MRBWMD
27 decides upon reservoir operations with consideration of those recommendations. The
28 updated Work Plan is then released, reviewed, and finalized according to the process
29 identified in Section 2.4.4.

30 Some decisions must be made in near real-time rather than during the annual cycle.
31 Activities such as habitat modification techniques and predation control may need to be
32 responsive to conditions on the river; while they are anticipated and planned for in
33 advance, details of their implementation will be made by implementation staff during
34 the construction or nesting seasons. Real-time decisions regarding flow modifications
35 for habitat or flow management to reduce take are made by MRBWMD.

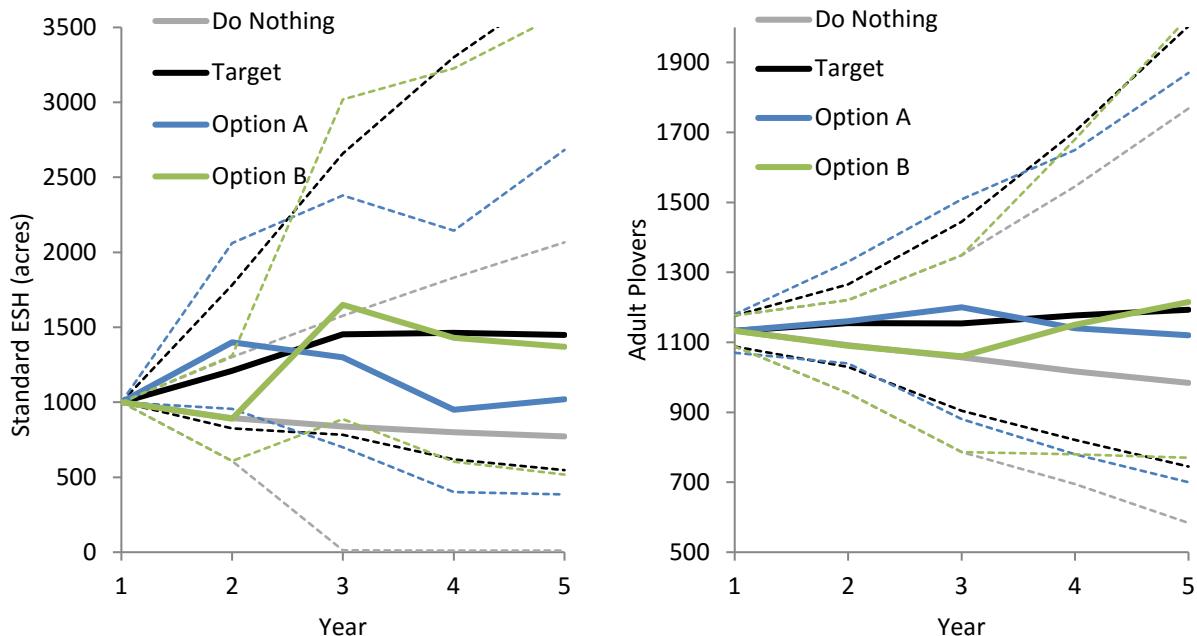

1 **3.6.2 Information for making decisions**

2 The Annual AM Report includes descriptions of the habitat and species status and needs
3 (Section 3.5.3) and management conditions (Section 3.5.4) which provide a starting
4 point for what is needed and what is possible in upcoming years. The report also
5 includes updated assessments of management action effectiveness that the Bird Team
6 will consider. In addition to this information, the Technical Team provides modeling of
7 potential management options as decision support tools.

8 **3.6.2.1 *Model projections of management options***

9 Depending on the set of available management actions, there may be more than one
10 means of meeting bird objectives and targets, including different actions or different
11 implementation of actions in time or space. The most effective and efficient combination
12 may not be readily apparent, particularly when interactions and natural variability are
13 taken into account. Predictive models can help to determine the optimal combination
14 and intensity of each management action. Incremental benefits of additional
15 management actions or increased effort can be compared with the incremental costs and
16 impacts. In cases where available management options are not expected to meet targets,
17 models can also be used to estimate the impact in future years of short-term shortfalls.
18 This information can be used at the programmatic level to estimate future resource
19 needs and priorities. Once a set of management options has been identified, the
20 predictive models are used to project the expected distribution of habitat and population
21 outcomes for each management option and a “do nothing” baseline comparison. These
22 projections indicate which alternative comes closest to the target trajectory.

23 A hypothetical example comparing two management actions with the target trajectory
24 and a do-nothing scenario is shown in Figure 56. The scenarios approximate a resource-
25 limited case. Option A uses limited funding to build habitat, but maintaining the target
26 acreage is not possible. Option B uses a flow release to create habitat when conditions
27 allow (prior to year 3) and uses resources to maintain as much of that acreage as
28 possible. Bird populations fare better in the first three years with Option A, but then
29 begin to decline. The population in Option B is not on path to meet targets until year 4
30 but has habitat and population trajectories very near the target scenario by year 5.

1 Figure 56. Model projections of a) standard acres and b) adult plovers for two hypothetical management
 2 options, compared to a target trajectory and doing nothing. Solid lines are median results of 5,000 model
 3 replicates. Dashed lines are 95% confidence intervals.

4 While this invented scenario is a simplification, it illustrates the importance of using
 5 models to compare outcomes across multiple time scales. The use of confidence
 6 intervals is also important: while it is expected that the plover population will do better
 7 with Option A or B than doing nothing, there is a large overlap in the confidence
 8 intervals and it thus cannot be known for certain that one scenario would outperform
 9 another in real-life application. The probability of success, however, will likely be
 10 different and such probabilities should be explicitly stated and used in the decision
 11 making process. All comparisons used for the basis of decisions are probabilistic and
 12 must be interpreted in the context of acceptable levels of certainty and risk.

13 3.6.3 Management action decisions

14 Most decisions about which actions to implement, when, where, and how are multi-
 15 factor decisions. While quantitative criteria can be developed (e.g. how much ESH to
 16 create to have a specified likelihood of meeting the target, according to the models),
 17 most decisions cannot be simplified to single criteria or triggers. In this section we
 18 outline the considerations for implementing management actions. These include flow
 19 modifications analyzed in the MRRMP EIS but not included in the Preferred
 20 Alternative. The considerations are given as a series of questions that should be
 21 answered prior to making a decision. Quantitative criteria for individual factors and
 22 multi-criteria decision analysis tools to weight multiple factors can be developed if more

1 quantitative and formal tools are determined to be helpful. Additional tools could be
2 formalized through the AM process if deemed useful.

3 Evaluations of HC factors related to implementing flow modifications for birds are
4 described in more detail in Chapter 5 and referenced but not reproduced here.

5 3.6.3.1 *Decisions about how to create habitat*

6 The Annual AM Report includes estimates of the amount of ESH, if any, that needs to be
7 created. Once the need has been determined, the decision scope is outlined by
8 answering these questions:

- 9 • What is the capacity for implementing mechanical ESH creation in the next 1-5
10 years, taking budget, logistics, possible flow releases, and other constraints into
11 account?
 - 12 ○ What habitat distribution is expected to result if construction were fully
13 implemented?
 - 14 ○ What habitat distributions would be expected if construction could not occur in
15 specific years due to fall releases > 35 kcfs? If budget was not sufficient in one
16 year? Etc.
- 17 • Are flow actions to create ESH part of the current set of actions?
 - 18 ○ If yes, how likely is it that reservoir storage will allow for habitat-forming releases
19 in the next 5 years?
 - 20 ○ What habitat distribution is expected to result from a release?
 - 21 ○ If no flow action is available, under what circumstances would a flow test be
22 considered?

23 While neither future budget nor reservoir storage and releases can be known with
24 certainty, the 5+ year time frame allows for more thorough considerations of timing,
25 including whether more intensive near-term management may be needed to buffer
26 against any reduced ability to act in the future.

27 If there is a choice between whether to implement flow actions or mechanical creation
28 or how to combine the two, the following questions should be answered:

- 29 • *How much ESH is currently present?* Flow releases to create ESH provide the
30 greatest benefit when ambient ESH area is low, as more ESH is created for any given
31 flow release. If large amounts of ESH are available, flow releases may provide little
32 or no benefit.
- 33 • *What is the degree of need for ESH?* If larger amounts of habitat are needed, flow
34 creation may be more effective, especially if costs of construction are prohibitive. For

1 smaller shortfalls in ESH, benefits gain from flows may not outweigh potential risks
2 or conflicting water use.

- 3 • *What is the degree of need for the bird population?* Lower risks to the bird
4 population and some other objectives favor the use of habitat construction rather
5 than flow releases, if feasible.
- 6 • *Are there competing uses of storage that might preclude habitat-forming releases?*
7 The ability to meet multiple use needs including sturgeon management actions and
8 HCs should be weighed along with benefits to ESH.
- 9 • *What are the anticipated human considerations effects?* Estimated impacts and
10 benefits from a habitat-forming flow should be considered (see Chapter 5 for more
11 detail.)
- 12 • *Are there synergistic uses of flow actions?* Flows that meet multiple purposes
13 receive higher priority than those that only create ESH.
- 14 • *What is the likelihood of flows allowing construction?* High releases may preclude
15 construction.
- 16 • *What is the likelihood that the flow release will be successfully implemented?*
17 Planning for a flow, and then being unable to implement it, causes a delay in overall
18 habitat creation.
- 19 • *Are there learning opportunities from implementing a flow release? What is the
20 expected value of the information?* Initially most flow releases will provide uniquely
21 valuable information, but some may provide more critically needed information than
22 others and are opportunities for active AM.
- 23 • *Are there learning opportunities from implementing construction? What is the
24 expected value of the information?* While there is less uncertainty about
25 construction, learning opportunities may arise that would prioritize construction
26 over flow creation.

27 Answers to these questions provide a qualitative decision basis and aid in documenting
28 decisions. More specific criteria and/or quantitative criteria may be developed in the
29 future.

30 Decision and collaboration level: The Management Team decides whether to implement
31 construction or recommend flows (or both, over the multi-year Work Plan). If flows are
32 recommended, Water Management at the Oversight level must make the decision and
33 informs and review actions with MRRIC as described in Section 2.4.2.

34 3.6.3.2 *Decisions about constructing habitat*

35 Mechanical construction also requires additional decisions of how much to build within
36 each reach, and at what specific locations.

- 1 • *How much ESH is needed to meet targets in each reach?* Habitat targets are
2 specified separately for the north and south regions (Garrison in the north and
3 Fort Randall and Gavins Point in the south), so the ESH needed for each region
4 can be determined. ESH availability may or may not be in sync between regions,
5 so priority may be given to one region over another.
- 6 • *What is the population status in each region?* Assessments of population density,
7 fledge ratios, and population growth rates within each region should be assessed
8 to determine if one region should receive more habitat creation effort.
9 Demographic targets are prioritized over meeting ESH targets.
- 10 • *Are there constraints that limit ESH construction in any reach in the next 1-5*
11 years? Construction activities for the current FY are already contracted during
12 the decision making cycle; if it appears that construction may not be possible, e.g.
13 due to higher fall releases, additional construction should be planned for future
14 years to compensate. Logistical considerations may result in construction that is
15 suboptimal from a target perspective but still beneficial.

16 The numerical models can be used to predict the expected outcome of different
17 construction strategies. Moreover, the agencies may agree to accept the risk of
18 constructing to a level less than target in a given year (due to budget constraints, for
19 example), or to build more than needed to meet targets as a hedge against the risk that
20 conditions in that or future years might limit availability. Such strategies, however, may
21 be inefficient and more costly over longer time periods.

22 Decision and collaboration level: The Bird Team and associated implementation staff
23 decides where to construct ESH, in coordination with states, tribes, and other agencies
24 as needed.

25 3.6.3.3 *Decisions about how to create habitat through flows*

26 Decisions about when and how to implement habitat-forming flows (should they be
27 included in a ROD and ensuing revisions to the Master Manual) would be driven by ESH
28 need and HC-focused decision criteria. Multiple options for creating ESH may be
29 available and should be assessed with the following questions, supported by modeling:

- 30 • *What is the expected amount of ESH created by a potential flow release?* Flows
31 of higher magnitude and/or longer duration create more ESH. Constraints on
32 magnitude and duration are included in the action definition. The amount of
33 ESH prior to the flow release will also affect the amount created, and the amount
34 available during future nesting seasons will depend upon the intervening flows.
- 35 • *What is the expected bird response to a potential flow release?*
- 36 • *What are the expected effects on pallid sturgeon?*
- 37 • *What are the expected impacts to HCs?* See Chapter 5

- 1 • *What are the expected benefits to HCs? See Chapter 5*
2 • *Under what conditions would flow modifications be reduced or stopped during*
3 *implementation? See Chapter 5*

4 Adjustments to the timing of flow releases (which years, and when during the year) can
5 be used to reduce expected impacts and increase expected benefits. Tradeoff analyses
6 may be necessary to support these decisions and are described in Chapter 5.

7 Decision and collaboration level: If flow modifications are recommended by the
8 Management Team, MRBWMD must make the decision about how to implement flows
9 and informs and review actions with MRRIC as described in Section 2.4.2.

10 3.6.3.4 *Decisions about modifying existing habitat and vegetation removal*

11 Deciding to modify existing habitat (sandbar augmentation/modification and/or
12 vegetation management) is largely a case-by-case decision based upon observations at
13 individual sandbars.

- 14 • *Is early-successional vegetation present and above water after the breeding season*
15 *ends? Vegetation removal is more efficient at early successional stages, so in most*
16 *cases removal is warranted to preserve the useful lifetime of ESH.*
17 • *Are there constraints on the use of vegetation removal techniques at a location?*
18 Regulations or HCs may affect the use of vegetation removal at some sites.
19 • *Is foraging habitat limiting on sandbars that have suitable nesting habitat?*
20 Consider reshaping to provide more foraging habitat.
21 • *Can low-elevation sandbars be built up to provide nesting habitat that is less*
22 *vulnerable to inundation? Consider augmentation or overtopping to provide habitat*
23 *with less inundation risk.*
24 • *Has predation or human activity been prevalent on a sandbar, impacting bird*
25 *productivity? Consider not maintaining habitat that may be attractive to nesting*
26 *birds but results in high mortality due to recurring disturbances. Vegetation removal*
27 *may reduce risk from some predators, but not all.*

29 Decision and collaboration level: The Management Team decides on the budget
30 available for habitat modification, as informed by the Technical, Bird, Fish and HC
31 Teams. Implementation staff decides on location, methodology, design and contracting
32 based upon identified best practices. MRRIC is informed through the work plan.

33 3.6.3.5 *Decisions about whether to lower nesting season flows*

34 Lowered summer flows expose more ESH and thus can be used to increase habitat
35 availability to meet targets, especially when enough ESH cannot be created. The amount

1 of lowering required to have a beneficial effect depends on how much ESH is available
2 and its elevation. Some flexibility to manage lower flows during the nesting season
3 exists within the current technical criteria in the Master Manual. Factors for these
4 decisions include:

- 5 • *How much standardized ESH is currently present?* If there is very little ESH
6 available and little additional habitat to be exposed, the benefit of reducing flows
7 may not outweigh impacts. If there is abundant habitat and population density is
8 low, lowered flows have little benefit. Benefits are maximized at low-moderate
9 amounts of ESH with high population densities.
- 10 • *How well have habitat availability targets been met in recent years?* A higher need
11 for meeting habitat availability target supports lowering nesting season flows.
- 12 • *What are the projected flows absent additional modification?* The availability of
13 ESH given projected flows may be sufficient to meet needs without further
14 modification. Comparison of the expected flows to downstream needs informs how
15 much flexibility there may or may not be to alter flows.
- 16 • *Are there synergistic use of lowered flows?* Flows that meet multiple purposes (e.g.
17 benefits to pallid sturgeon; benefits to conserving water in reservoirs) receive higher
18 priority than those that only create habitat.
- 19 • *How will reservoir populations be affected?* If the sub-populations nesting on
20 reservoir shorelines are doing well, short-term impacts from holding back water in
21 the reservoirs will have low impact on long-term viability of the northern population.
- 22 • *Are there competing uses of storage that might preclude habitat-forming releases?*
23 See Chapter 5
- 24 • *What are anticipated human considerations impacts?* See Chapter 5

25 Decision and collaboration level: Collaboration on lower nesting season flows within
26 current Master Manual criteria follows the AOP process and would be included in the
27 WP as time permits. If lowered summer flows as a deliberate, planned activity are added
28 to the ROD, adjustments to the Master Manual may be required to accommodate more
29 substantive flow management. To modify the action, a high level of collaboration would
30 occur and those decisions would be made at the Oversight level (see Section 2.4.6.5).

31 3.6.3.6 *Decisions about predation management*

32 Deciding to implement predation management is largely a case-by-case decision based
33 upon history and observations at individual sandbars and landscape characteristics,
34 though overall population density can help rate the risk of predation and value of
35 management.

- 36 • *Has predation been observed on a sandbar/segment in the past?*
- 37 • *Is there evidence for predation occurring during this nesting season?*

- 1 • *Is the population density above thresholds where predation is more likely?*
2 • *Do landscape features (vegetation cover, nearby trees) support predators?*
3 • *Is the sandbar attached to shore in the anticipated range of flows during the
4 nesting season?*

5 **Decision and collaboration level:** The Bird Team estimates the degree of predator
6 control needed as informed by the Technical Team's projection of population density.
7 Implementation staff decide on amount and locations based on ongoing monitoring
8 during the season.

9 **3.6.4 Decisions related to experiments and research activities**

10 Opportunities for experimental implementation of management actions can be
11 exercised to develop more productive, efficient, and cost-effective means of achieving
12 the bird objectives. Learning can be accelerated by implementing an action in different
13 ways (e.g. testing and monitoring of different sandbar designs) or implementing actions
14 to broaden the available data, allowing for more definitive hypothesis testing (e.g.
15 implementing flows across a range.) This may include *not* implementing an action that
16 may be otherwise recommended if the information to be gained is sufficiently
17 important. Decisions about experimental design and research implementation are based
18 on the following considerations:

- 19 • *What data gaps need to be addressed? What hypotheses require more evidence?*
20 Regular evaluation of evidence for management hypotheses will identify the need
21 for research and the specific questions that should be addressed.
22 • *What is the expected value of the information?* Learning resulting in greater
23 gains in the efficiency and effectiveness of management should be prioritized.
24 Modeling can help quantify potential benefits of research or experiments.
25 • *Are there additional benefits to experimental implementation?* Projects may
26 help answer other science questions, enable other research, or provide HC
27 benefits.
28 • *Does the experimental design increase the likelihood or magnitude of HC
29 impacts?* The potential for impacts not normally associated with an action, or an
30 increase of known impacts, should be evaluated and additional
31 monitoring/analysis, if needed, identified in advance.
32 • *Are there conflicts or constraints that may preclude completion of the
33 experiment?* For multi-year experiments, the ability to complete the project may
34 be more or less certain or require tradeoffs with other activities. Some
35 experiments may conflict, especially those that include flow modifications.
36 • *What additional monitoring of outcomes will be necessary, for how long, and
37 for what cost?* In some cases, it may be possible to assess the outcome of
38 experimental actions with the existing monitoring program; in other cases more

1 focused and/or intensive monitoring or monitoring of additional factors may be
2 required, possibly for multiple years.
3

4 Other research activities not directly connected to management actions (e.g. studies of
5 bird foraging ecology, dispersal, etc.) should receive similar consideration:
6

- 7 • *What data gaps need to be addressed? What hypotheses require more evidence?* Regular evaluation science questions and biological hypotheses will provide the
8 information necessary to identify the need for research and the specific questions
9 that should be addressed.
- 10 • *What is the expected value of the information?* Learning resulting in greater gains in the efficiency and effectiveness of management should be prioritized. Modeling can help quantify potential benefits of research or experiments.
- 11 • *Are there conflicts or confounding factors that may interfere with research or limit application of findings?* Not all factors can be anticipated, but planned
12 management actions or reservoir releases may affect the ability to perform
13 research, to carry out the full length of the intended study, or to interpret the
14 results.
15

16 Identified experimental and research actions will be prioritized based upon these
17 criteria and balanced with other management and research needs for funding and
18 implementation.
19

20 **Decision and collaboration level:** Collaboration on research and experimental
21 management actions will vary depending on the nature of the activity. Collaboration on
22 research activities will generally be through an annual needs elicitation (to which the
23 MRRIC may respond), the Fall Science Meeting and the Annual AM Workshop.
24 Decisions regarding which studies to fund will lie with the ISP Manager, subject to the
25 R&D budget provided in the Program. The Management Team proposes the R&D
26 budget in the draft Work Plan, but that figure is subject to approval and appropriations.
27 Collaboration on experimental implementation of management actions would generally
28 be consistent with any other implementation of that management action (see specific
29 action descriptions for examples) and go through the Work Plan process. Decisions
30 would generally be made by the Management Team with input from the Technical, Bird,
31 Fish and HC Teams, with consideration of any MRRIC recommendations. Decisions
32 regarding flow tests would be made by the MRBWMD.
33

36 **3.6.5 Decision criteria for when targets are not met**

37 The definition of targets in Section 3.2.3 includes the quantitative criteria and time
38 frames for meeting targets. There are a number of reasons that the program could fail to
39 meet targets over the specified time frames. Steps to solve the problem are associated

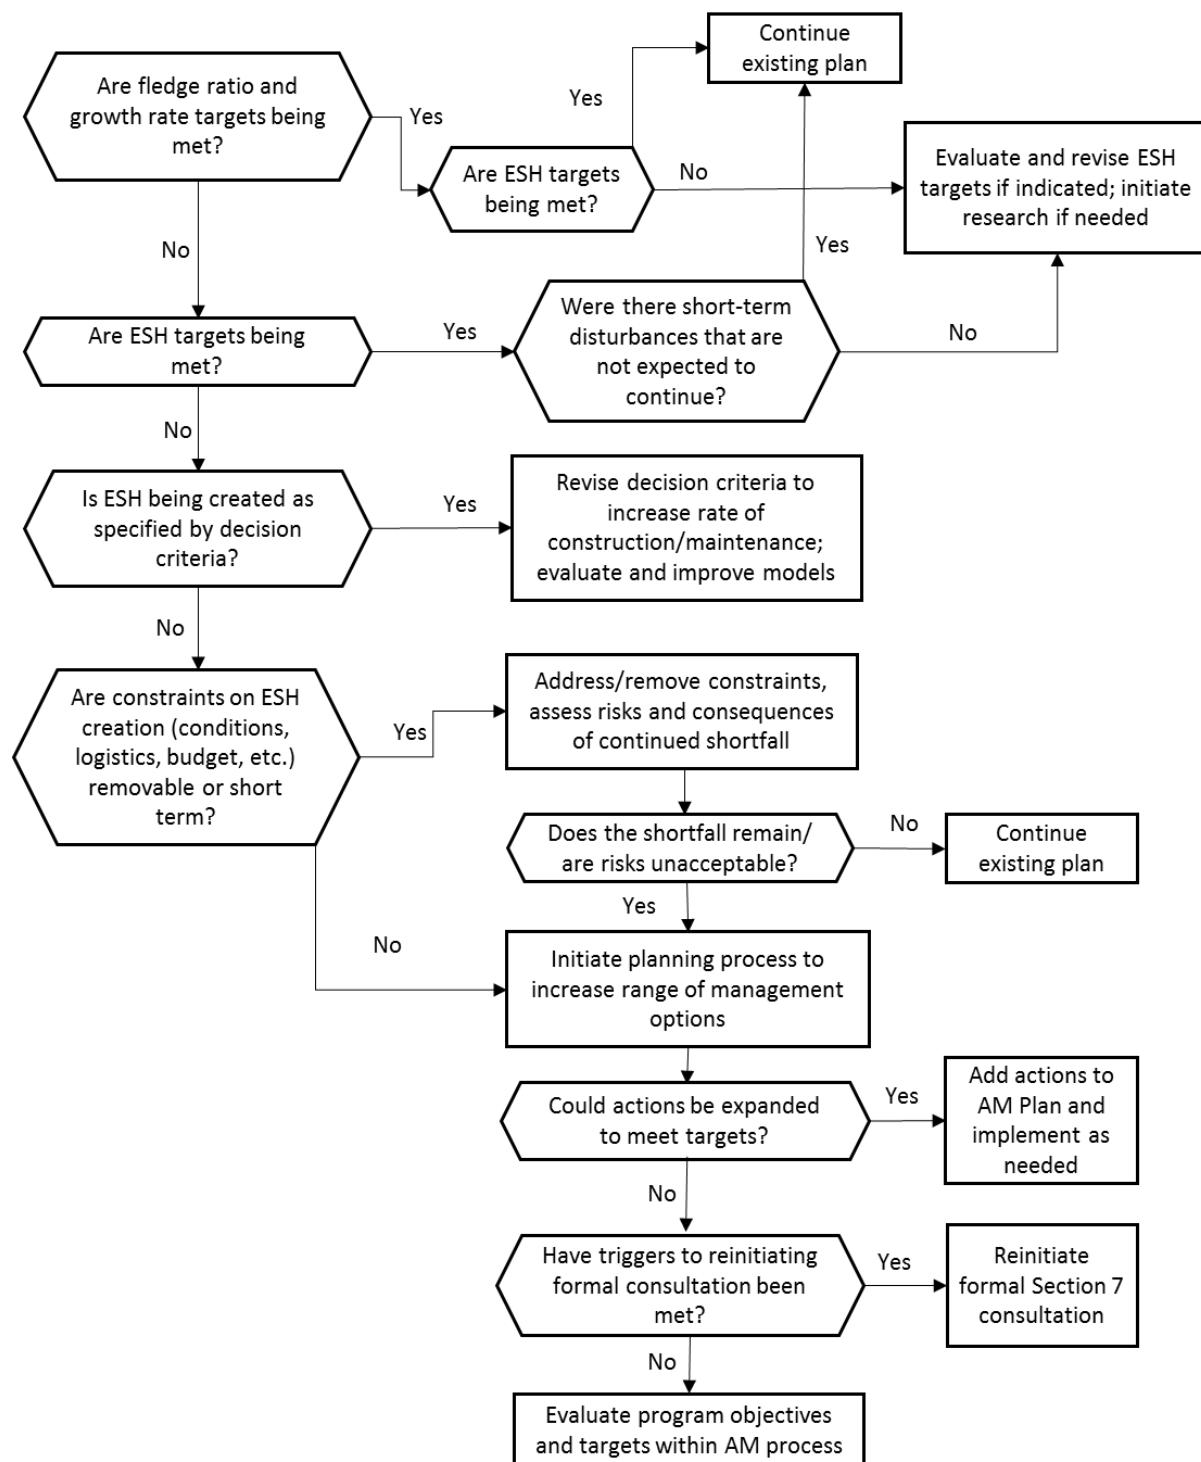

1 with each potential reason. The AM process is forward-looking and will attempt to
2 anticipate and remedy shortfalls before they occur with the use of predictive modeling
3 and adjustments to management actions in the Work Plan. In the case that problems are
4 not anticipated, or remedies cannot readily be implemented under existing program
5 operation, constraints, or priorities, the criteria described below outlines decisions or
6 decision processes that need to occur. While requirements for specific management
7 actions following failure to meet targets have not been established, decision criteria have
8 been or will be developed to facilitate the decision making process and ensure the
9 relevant scientific information is available and in useful form. These decision criteria do
10 not pre-specify the outcomes of decisions, only that the decision process be initiated
11 with sufficient time to address the problem and followed through to a determination of
12 necessary adjustments to the Work Plan or the AM Plan. While the process may
13 determine that no adjustments will be made, the decision criteria ensure that relevant
14 information is taken into account and the decision was made at the correct level(s).

15 The diagnostic process would be initially conducted by the Technical Team to identify
16 current or anticipated problems and their causes to the extent possible based on
17 monitoring and other program information; the Bird Team would review the diagnosis
18 and identify solutions to be approved by the Management Team or elevated to the
19 Oversight level. Generally, the Oversight level is responsible for deciding whether or not
20 to remove constraints on action implementation, add actions, or change objectives or
21 target criteria based on policy decisions (e.g. as opposed to updating target values based
22 on new data). Some changes would also require additional NEPA analysis and/or formal
23 consultation with the USFWS (Section 2.4.5). Changes to implementation processes or
24 criteria for existing actions within established constraints, or science-based adjustments
25 to target values may not require Oversight approval.

26 Figure 57 illustrates the series of diagnostic questions for determining why targets are
27 not being met and steps to take to remedy the problem and improve future
28 performance. Problems are listed starting with questions based on scientific
29 understanding and moving to questions about program design and acceptance of risk. It
30 is possible that there may be more than one problem at any given time, but it may be
31 necessary to correct some problems before addressing others (e.g. must be able to fully
32 implement habitat creation guidelines before determining if the creation criteria are
33 sufficient.) Each question and associated recommendation for resolution are described
34 in more detail below Figure 57.

35

36

1

2 Figure 57. Diagnostic decision tree for a) determining why bird targets are not being met, and b) identifying
3 recommended corrective actions.

4 1. Are fledge ratio and growth rate targets being met?

5 a. Criteria: Fledge ratio growth and population growth time frames as
6 specified in targets (3-year arithmetic and geometric means, respectively).

- 1 b. *If yes*, the existing program is sufficient and should be continued.
2 However, it is also possible that demographic targets are being met but
3 ESH targets are not. If this occurs over multiple years (to account for time
4 lags in population responses) then ESH targets may be higher than than
5 they need to be and should be assessed and revised if appropriate. **Action:**
6 **continue program, revise ESH targets if information suggests they are**
7 **higher than needed to meet demographic targets.**
- 8 c. *If no*, continue to question 2.

9 2. *Are ESH targets being met?*

- 10 a. *Criteria*: Median standard ESH target is met 3 out of 4 years; available
11 ESH target meeting exceedance criteria over 12-year time frame.
- 12 b. *If yes*: ESH targets may not be high enough either due to insufficient data
13 when targets were set, or because conditions have changed. Targets should
14 be updated with new information; if new information is not available,
15 additional research or monitoring to improve targets should be identified.
16 It is also possible that unusual circumstances (disturbances) lowered
17 demographic rates despite sufficient habitat. If circumstances are
18 identified and not expected to persist, ESH targets may be retained.
19 **Action: evaluate controlling factors, disturbances, and ESH targets;**
20 **revise ESH targets if the shortfall is not caused by short-term**
21 **disturbances, initiate additional research if needed to inform models**
22 **and target calculations.**
- 23 c. *If no*: continue to question 3.

24 3. *Is ESH being created as specified by decision criteria and model estimates?*

- 25 a. *Criteria*: Meeting habitat creation guidance for 4 out of 5 years
26 (construction rates estimated by model to have 60% chance of meeting
27 targets; criteria for implementing flow actions if available).
- 28 b. *If yes*: Habitat creation guidance criteria is structured to provide sufficient
29 habitat to meet targets given uncertainty in geomorphological
30 understanding and future flows. If habitat is insufficient in the long term
31 after levels of habitat creation specified by the criteria have been met or
32 exceeded, then the models have bias that needs to be corrected and/or
33 assumptions about the hydrograph is incorrect (e.g. flows are in the highly
34 erodic range more often than in the past due to changes in management,
35 basin runoff, or changes in channel morphology and sediment budgets.)
36 Construction estimates can be adjusted to accommodate bias/uncertainty
37 until models can be improved. **Action: Adjust habitat creation criteria**
38 **to accelerate construction. Evaluate models for sources of bias in**
39 **habitat estimates; initiate additional research if needed to improve**
40 **models.**
- 41 c. *If no*: continue to question 4.

- 1 4. *Are the factors constraining ESH creation (conditions, logistics, budget, etc) removable or short-term?*
 - 2 a. *Criteria:* Constraints are short-term if not expected to occur more than 1 out of 5 years
 - 3 b. *If yes:* Constraints and/or conflicts are not allowing the current set of actions to be conducted to the necessary extent. If constraints can be removed by changes to practices, water management, regulations, or changes in priority, than the problem may be resolvable without changes to the set of actions available for use. Other limitations may be known to be limited in term and not expected to recur. **Action: Remove constraints and assess risks and consequences of continued shortfall by any combination of remaining or anticipated future constraints.** Continue to Question 5.
 - 4 c. *If no:* continue to Question 6.
- 5 5. *Do shortfalls remain/are risks unacceptable?*
 - 6 a. *Criteria:* Risk acceptability varies over time, by interest group, and circumstantially. The MRRP will seek to identify (and periodically update) appropriate criteria through the AM process.
 - 7 b. *If yes:* The current set and definitions of management actions is not sufficient to meet targets. A broader scope of existing actions and/or the addition of new actions will be necessary to meet objectives. **Action: Initiate planning process to increase range of management options (see sections 2.4.5 and 3.6.6)**
 - 8 c. *If no:* continue to question 6.
- 9 6. *Can the set of or specifications of actions be expanded to meet targets?*
 - 10 a. Results of tradeoff analysis and NEPA processes (as appropriate) indicate actions may be added or expanded in scope
 - 11 b. *Criteria:* Specific criteria not identified at present. Criteria development will be a consideration during the transitional period between the DEIS and establishment of the ROD.
 - 12 c. *If yes:* add actions to AM Plan, develop necessary decision criteria, and implement as needed and appropriate
 - 13 d. *If no:* continue to Question 7
- 14 7. *Have conditions for reinitiating formal consultation been met?*
 - 15 a. *Criteria:* Formal consultation may be reinitiated if “new information reveals effects of the agency action that may affect listed species or critical habitat in a manner or to an extent not considered in this opinion” (USFWS 1996)¹. That is, the proposed action evaluated by the Biological Opinion included the current targets and associated decision criteria; if

¹ This criteria for reinitiating formal consultation is most relevant to failure to meet targets. There are three additional criteria listed in Section 3.6.7.3.

1 not met, the USFWS must determine whether the previous consultation is
2 still sufficient.

- 3 **b. If yes: Action: reinitiate formal consultation under Section 7 of the**
4 **ESA.**
- 5 **c. If no: Action: revisit program objectives and targets within Oversight**
6 **Level with support from the Bird Team and Technical Team.**

7

8 **3.6.6 Decisions to add, change, or remove management actions**

9 Decisions to change how actions are implemented or to add new actions can be
10 triggered by a) new evidence for action effectiveness, b) new evidence indicating
11 expected impacts that precluded an action are sufficiently unlikely, c) regulatory
12 changes that allow additional/broader actions or d) evidence that targets cannot be met
13 with existing actions, thus requiring consideration of expanding the set of available
14 actions.

15 The decision to add actions is supported by tradeoff analysis, balancing evidence for
16 action effectiveness and for HC impacts and benefits (see Section 2.4.5.2). Cost-
17 effectiveness should also be considered, though the toolbox approach described in
18 Section 3.2.1 includes maintaining a range of management actions for use, even less
19 efficient ones, when the most cost-effective options may not be implementable.

20 If targets cannot be met using actions currently in the ROD and no additional
21 constraints upon their use can be reduced or removed, addition of actions outside of the
22 ROD should be considered before evaluating targets or reinitiating formal Section 7
23 consultation (Figure 57). This process also requires trade-off analyses or other
24 structured decision techniques (Section 2.4.5.2).

25 Criteria for changing individual actions are included in Section 0. The process for
26 adding actions, particularly flow management actions, is described in Section 2.4.5.
27 Actions may also be adjusted during implementation, though they may only be
28 increased in magnitude during implementation to the extent that the action was defined
29 within the programmatic EIS or site-specific assessments. Increase in action
30 specifications for future uses outside of what has previously been analyzed in the EIS
31 would require additional analysis and a decision document before implementation.

32 Decisions to stop an action during implementation can be triggered by approaching
33 identified HC thresholds (see Chapter 5) or indications that an action is no longer
34 effective or needed. Decisions to reduce the scope of an action or not use it in the future
35 may occur if there is sufficient weight of evidence that an action is not effective or
36 following an evaluation of HC impacts (see Chapter 5). The decision to remove an action

1 from future consideration requires cost-benefit determinations under a variety of
2 scenarios that weigh the use of the action against other alternatives. Low cost, low
3 impact actions may be retained even if less effective than other actions, as they may be
4 useful in cases where resources or conditions do not allow more effective action.

5 **3.6.7 Decisions to change metrics and targets**

6 The process to change metrics and targets depends on the type of change required.
7 Updates to metrics and target values (using the same criteria) are science-based and
8 expected to keep pace with new information with regular updates. Changes to target
9 criteria and or objectives are largely based on policy, risk tolerance, and values and
10 expected to be infrequent. These processes and the information or events that trigger
11 them are described below.

12 **3.6.7.1 Updates of habitat and fledge ratio targets**

13 Target values (e.g. acres of ESH, fledge ratios) are developed using the ESH and
14 population models and, consequently, reflect the current level of quantitative
15 understanding. As management, monitoring and research continue, the models will be
16 updated to reflect learning and provide more accurate estimates of habitat and
17 population dynamics, habitat requirements by nesting birds, and population
18 persistence. Periodically, ESH targets should be recalculated to reflect updated
19 information—i.e. every 5 years for incremental changes or more frequently if there are
20 major updates or revisions to models. Note that most changes to either the population
21 model (e.g. survival rates) or the habitat or hydrological models would change
22 calculated ESH targets. ESH targets should be recalculated often enough to allow
23 learning to improve management outcomes, but not so frequently as to hinder
24 reasonable planning and assessment processes. These updates can correspond with
25 broader periodic programmatic reviews. Large increases in information—for example,
26 completion of a research study that allows for significant model improvements—may
27 justify interim updates, pending agreement at appropriate decision levels. Decisions
28 follow the process outlined in Section 2.4.2.

29 Similarly, new information about demographics, particularly survival rates, would
30 indicate that the fledge ratio target would need to be updated. This value should be
31 periodically assessed and interim updates may be warranted following significant
32 science findings.

33 It is important to note that these updates are to the quantitative value of the targets for
34 the existing target criteria, not changes to the criteria themselves. These changes are
35 informed by the data available, are not policy- or value-based, and are expected to occur
36 more frequently than changes to the criteria themselves.

1 For the periodic updates to targets as described above, the Technical Team provides the
2 information about revised target values to the Bird Team, who in turn include request
3 the for adjustment in their recommendation to the Management Team. Updates to the
4 values are approved by the Management Team, who informs the Oversight level of the
5 change and resulting changes to the Work Plan. This update does not require Oversight
6 approval. If either the Bird Team or the Management Team declines to recommend
7 updating the targets, or recommends/approves an updated value that differs from the
8 recommendation of the Technical Team, the original proposal is presented at the next
9 MRRIC meeting along with the basis for the deviation (see the “chain of custody”
10 discussion in Section 2.4.6.1). Agency leadership may consider this information and
11 render a final decision regarding the targets. The MRRIC may make a recommendation
12 regarding the adjusted value.

13 *3.6.7.2 Revisions to metrics*

14 Increased scientific understanding may also result in changes to how habitat or
15 populations are measured in the context of objectives. This includes changes to how the
16 fledge ratio or habitat quantification is defined. Changes to metrics may be necessary if
17 either scientific understanding has changed such that the assumptions underlying the
18 metrics are no longer accurate, or if the monitoring program is unable to capture the
19 metric sufficiently and cannot feasibly be improved. As with the quantitative values of
20 targets this does not necessarily reflect a change in the criteria themselves. The
21 Technical Team and Bird Team, individually or together, may recommend a change to
22 metrics to be decided upon at the Management Team level.

23 *3.6.7.3 Revisions to objectives and target criteria*

24 The species objectives and target criteria (unlike their numerical values) are policy
25 decisions based upon agreements of acceptable levels of risk and priorities and
26 applicable regulations. These decisions can be informed by modeling and other scientific
27 information (such as metapopulation dynamics), but are fundamentally values-based
28 decisions made at the Oversight level. Objectives and targets should be re-evaluated
29 periodically or if risk tolerance, management priorities, and/or regulations change
30 significantly. The following target criteria are subject to this level of decision:

- 31 1) Population persistence criteria: the quasi-extinction threshold, probability of quasi-
32 extinction, and time frame. Higher quasi-extinction thresholds, lower probabilities,
33 and longer time frames reduce risk to the population and increase management
34 requirements (see Buenau 2015 for examples.) Lower thresholds, higher
35 probabilities, and shorter time frames increase risk to the population and reduce
36 management requirements.

- 1 2) Time frames for meeting targets: the definition of the targets allows them to be
2 missed on occasion as long as targets are met in most years (i.e. 3 out of 4 years for
3 standard ESH targets and for 3-year averages for demographic targets.) This allows
4 for short-term disturbances (e.g. high flow years that limit nesting) as part of the
5 natural variability of the river. They allow for limited shortfalls in management but
6 not persistent limitations. Changing the frequency that targets must be met will
7 change the level of risk to the population.
 - 8 3) Confidence bounds: upper and lower confidence bounds trigger larger adjustments
9 to management activities when habitat acreage falls outside rather than within them.
10 These bounds are probability-based but fundamentally a decision based on risk
11 tolerance, and can be adjusted. The lower bound indicates what likelihood of failure
12 to meet population objectives must be met before more intensive habitat creation
13 needs to occur (potentially at higher cost and/or pre-emption of other priority
14 activities.) Increases to the lower bound reduce the risk of failure to meet objectives,
15 while increasing costs and other impacts. The upper bound indicates the point at
16 which too much habitat is being created relative to what is likely needed, and the
17 costs or other impacts are higher than necessary. Lowering that bound places high
18 value on keeping costs and impacts low, with increased risk of not meeting
19 population objectives.
- 20 Changes to objectives are a more fundamental step and may be triggered by regulatory
21 or other policy changes (e.g., to USACE authorities) or broad changes in scientific
22 understanding, e.g. how the Missouri River subpopulations of plovers relate to the
23 larger population. They may also require adjustment to reflect any driving factors
24 outside of USACE control that limit the ability to manage the Missouri River
25 subpopulations, such as factors affecting survival or physical condition when birds are
26 using winter habitat.
- 27 An inability to meet targets may trigger re-evaluation of target criteria and objectives
28 (Section 3.6.5). However this step should be taken only after other solutions have been
29 attempted and if it has been determined that no adjustments to the program could be
30 made that would meet the targets. Changes to objectives or target criteria may require
31 reinitiation of formal consultation.

4₁ Adaptive Management of Pallid Sturgeon in the 2 Missouri River

- 3 This chapter is organized according to the steps of the AM cycle introduced in
4 Section 1.1.5:
- 5 1. Assess (Section 4.1), which provides goals and objectives for pallid sturgeon, and also
6 summarizes the EA (Jacobson et al. 2015a, 2015b, 2016a, 2016b; Delonay et al.
7 2016b);
- 8 2. Plan and Design (Section 4.2), which summarizes metrics and decision criteria for
9 Level 1 and Level 2 components, and describes the design of Level 3 actions
10 (including hypotheses, action descriptions, objectives, expected benefits, metrics,
11 experimental design, decision criteria, and Level 3 contingent actions);
- 12 3. Implement (Section 4.3) describes the current schedule for implementation of Level
13 1, 2 and 3 actions. This schedule will be further revised over time.
- 14 4. Monitor (Section 4.4), which summarizes the metrics used for monitoring each Level
15 2 and 3 action currently under consideration;
- 16 5. Evaluate (Section 4.5), which summarizes the evaluation approaches used for each
17 Level 2 and 3 action; and
- 18 6. Decide (Section 4.6), which summarizes the decision criteria for each Level 2 and 3
19 actions.
- 20 7. Section 4.2 also incorporates much of the material from the Lower Missouri River
21 Pallid Sturgeon Framework, Targets and Decision Criteria (USFWS and USACE
22 2015, USFWS 2015a, USFWS 2016). This chapter is associated with several
23 appendices:
- 24 A. Appendix C contains details of the design of Level 1 and 2 actions.
- 25 B. Appendix D describes the protocol to be used for population monitoring, and the
26 structure of the population model that's closely associated with the population
27 monitoring
- 28 C. Appendix E [*in progress*] lists other monitoring protocols not contained in Appendix
29 C.
- 30 D. Appendix F contains detailed cost estimates for Level 1 and Level 2 science
31 components.
- 32

1 Relative to birds, there is a greater level of uncertainty about the most appropriate
2 management actions to maintain and recover pallid sturgeon populations in the
3 Missouri River. Therefore, the approach described in this chapter involves a greater
4 investment in research to reduce critical uncertainties that affect management
5 decisions, and in rigorous monitoring of well designed pilot actions (Level 2) to evaluate
6 their effectiveness.

4.1 Assess

4.1.1 Goals and management objectives for pallid sturgeon

9 In 2013, the USFWS (written com., September 12, 2013 [Draft Species Objectives, p. 1])
10 developed the following fundamental objective for pallid sturgeon in the Missouri River:

11 *Fundamental Objective: Avoid jeopardizing the continued existence of the pallid
12 sturgeon from the U.S. Army Corps of Engineers actions on the Missouri River.*

13 The USFWS notes that this objective is consistent with species recovery goals (U.S. Fish
14 and Wildlife Service, 2014) but specific to Missouri River management actions.

15 In 2013, the USFWS also proposed the following two sub-objectives (both measurable),
16 which must be attained to ultimately achieve the stated “fundamental objective”. The
17 intent of the sub-objectives is to provide direction in the short term, provide objectives
18 meaningful for AM, and focus efforts on the desired short term outcomes while keeping
19 the fundamental objective in mind. Although attaining a self-sustaining population is the
20 desired outcome of the Revised Pallid Sturgeon Recovery Plan (USFWS 2014), described
21 below under sub-objective 2, we may be decades away from such an objective being very
22 meaningful. If natural recruitment were achieved in 10 years, it could take 20 to 30 years
23 before progress toward the self-sustaining population objective could be assessed.
24 Modeling can give projections and insights into the probability of achieving the
25 fundamental objective under proposed and implemented actions. The two sub-
26 objectives provide guidance for the actions, monitoring and research required to
27 support the fundamental objective over the longer term.

28 *Sub-objective 1: Increase pallid sturgeon recruitment to age 1.*

29 **Metrics:** primary metric is catch rates of age 0 and age 1 pallid sturgeon; secondary
30 metrics include model-based estimates of abundance of age 0 and age 1 pallid sturgeon,
31 and the survival of hatchery and naturally reproducing fish to age 1.

32 **Target:** TBD. The short-term target is to demonstrate measurable recruitment to age 1,
33 and hopefully increasing levels of recruitment over time. Recruitment is emphasized in
34 sub-objective 1 since wild-spawned young-of-year (YOY) or juvenile pallid sturgeon have

1 not been captured in the Upper Missouri River upstream of Lake Sakakawea, and have
2 been captured only rarely in the Lower Missouri River (Jacobson et al. 2016a). Until
3 2015, there had been no documented captures of genetically identified, wild-spawned
4 pallid sturgeon free embryos, larvae, or YOY in the lower river (U.S. Fish and Wildlife
5 Service, 2014). Recent data indicate that limited recruitment is happening in the Lower
6 Missouri River, but not at a level sufficient to maintain the population (U.S. Fish and
7 Wildlife Service, 2014; Jacobson et al. 2016a). Multiple factors can potentially be
8 limiting recruitment (see Appendix B, Figures B.9, B.10 and B.11).

9 The long-term target for recruitment (i.e. necessary levels and frequency of recruitment
10 over time) will be informed by the EA (Jacobson et al., 2016a) and collaborative
11 population model (Section 4.1.2.3 and Appendix D of this plan), following the necessary
12 monitoring, model validation, and supporting research. Defining the long term target is
13 not critical in the near-term as the immediate priority is to establish measurable
14 recruitment. Possible targets could include a modeled egg to age-1 survival rates
15 sufficient to result in growth and sustainable population size.

16 *Sub-objective 2: Maintain or increase numbers of pallid sturgeon as an interim
17 measure until sufficient and sustained natural recruitment occurs.*

18 **Metric:** Population estimates for pallid sturgeon for all size and age classes, particularly
19 for ages 2 to 3 to assess recent trends in recruitment; catch rates of all pallid sturgeon by
20 size class (to maintain legacy data). Age classes will be estimated as an output metric of
21 the population model that will be validated through recaptures of tagged fish. There are
22 challenges in quantifying a population size for age 2-3 year old pallid sturgeon as there
23 is a lot of overlap in the lengths of fish aged 2 to 5 years. Further work is required to
24 refine population metrics, which may include estimating a population size for a subset
25 of the length frequency distribution.

26 **Target:** TBD. Possible targets could include: 1) positive population growth rates (i.e.,
27 lambda (λ) > 1) of pallid sturgeon age 2 and older; 2) estimated survival rates of all
28 size/age classes sufficient to provide a stable population of pallid sturgeon age 2 and
29 older; and 3) acceptable probabilities of persistence and recovery over a 50 to 100 year
30 time frame (utilizing population models). For example, the Lower Missouri Framework
31 (USFWS and USACE 2015) described two preliminary decision criteria for halting
32 population augmentation: 1) when population monitoring demonstrates a self-sustaining
33 population in excess of 5000 adult fish in each management unit; and 2) when the threat
34 of extirpation is less than 5 percent in 50 years, or as based on new criteria introduced
35 through the Basin-wide Stocking and Augmentation Plan. The criteria recommended in
36 USFWS and USACE (2015) are similar to those in the Revised Recovery Plan for the

1 Pallid Sturgeon for reclassifying pallid sturgeon from endangered to threatened status
2 (UFSWS 2014, pg. 54):

3 "Pallid Sturgeon will be considered for reclassification from endangered to threatened
4 when the listing/recovery factor criteria are sufficiently addressed such that a self-
5 sustaining genetically diverse population of 5,000 adult Pallid Sturgeon is realized and
6 maintained within each management unit for 2 generations (20-30 years). In this
7 context, a self-sustaining population is described as a spawning population that results
8 in sufficient recruitment of naturally-produced Pallid Sturgeon into the adult population
9 at levels necessary to maintain a genetically diverse wild adult population in the absence
10 of artificial population augmentation. Metrics suggested to define a minimally sufficient
11 population would include incremental relative stock density of stock-to-quality-sized
12 naturally produced fish (Shuman et al. 2006) being 50-85 over each 5-year sampling
13 period, catch-per-unit-effort data indicative of a stable or increasing population, and
14 survival rates of naturally produced juvenile Pallid Sturgeon (age 2+) equal to or
15 exceeding those of the adults (see Justification for Population Criteria below [in USFWS
16 2014] for details). Additionally, in this context a genetically diverse population is defined
17 as one in which the effective population size (N_e) is sufficient to maintain adaptive
18 genetic variability into the foreseeable future ($N_e \geq 500$), conserve localized adaptions,
19 and preserve rare alleles."

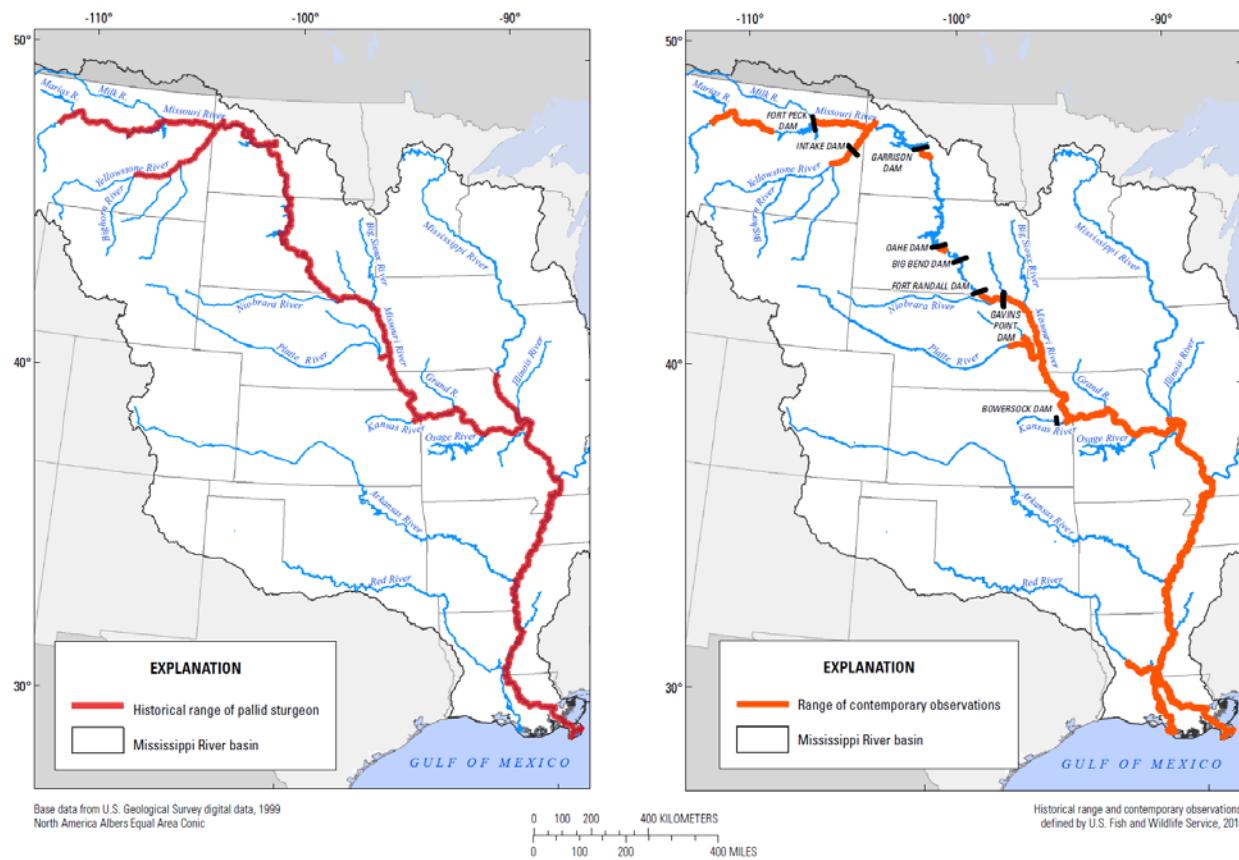

20 In addition to the fundamental objective and associated sub-objectives, there are a set of
21 proposed actions to be implemented on the Missouri River, which are the means of
22 achieving the fundamental objectives and sub-objectives. The timelines for these actions
23 serve as a backstop to ensure that the rate of implementation of management actions on
24 the Missouri River is not hindered by an inability to learn from applied science efforts.
25 In effect, they define necessary levels of implementation at a point in time for each
26 hypothesis, and must be met unless the learning from applied science efforts
27 demonstrates that the in-river actions associated with that hypothesis are unnecessary.

28 4.1.1.1 *Geographic scopes of the Effects Analysis, MRRP-EIS and this AM Plan*

29 The geographic scope of the Pallid Sturgeon EA was larger than the scope of the MRRP-
30 EIS and this AM Plan. The area considered in the EA included the Upper Missouri River
31 mainstem from Fort Peck Dam to the headwaters of Lake Sakakawea, the Yellowstone
32 River upstream of the confluence with the Upper Missouri River for an unspecified
33 distance, the Lower Missouri River mainstem from Gavins Point Dam to confluence
34 with the Mississippi River at St. Louis, tributaries used by pallid sturgeon, and an
35 unspecified distance downstream in the Mississippi River (Figure 58). The distance
36 downstream in the Mississippi River is unspecified because presently available
37 information (2015) is ambiguous about the extent to which Missouri and Mississippi
38 river populations mix through migrations and dispersal. Recent information suggests

1 that adult pallid sturgeon originating in the Missouri River are frequently found in the
 2 middle and upper Mississippi River (Porecca et al. 2015).

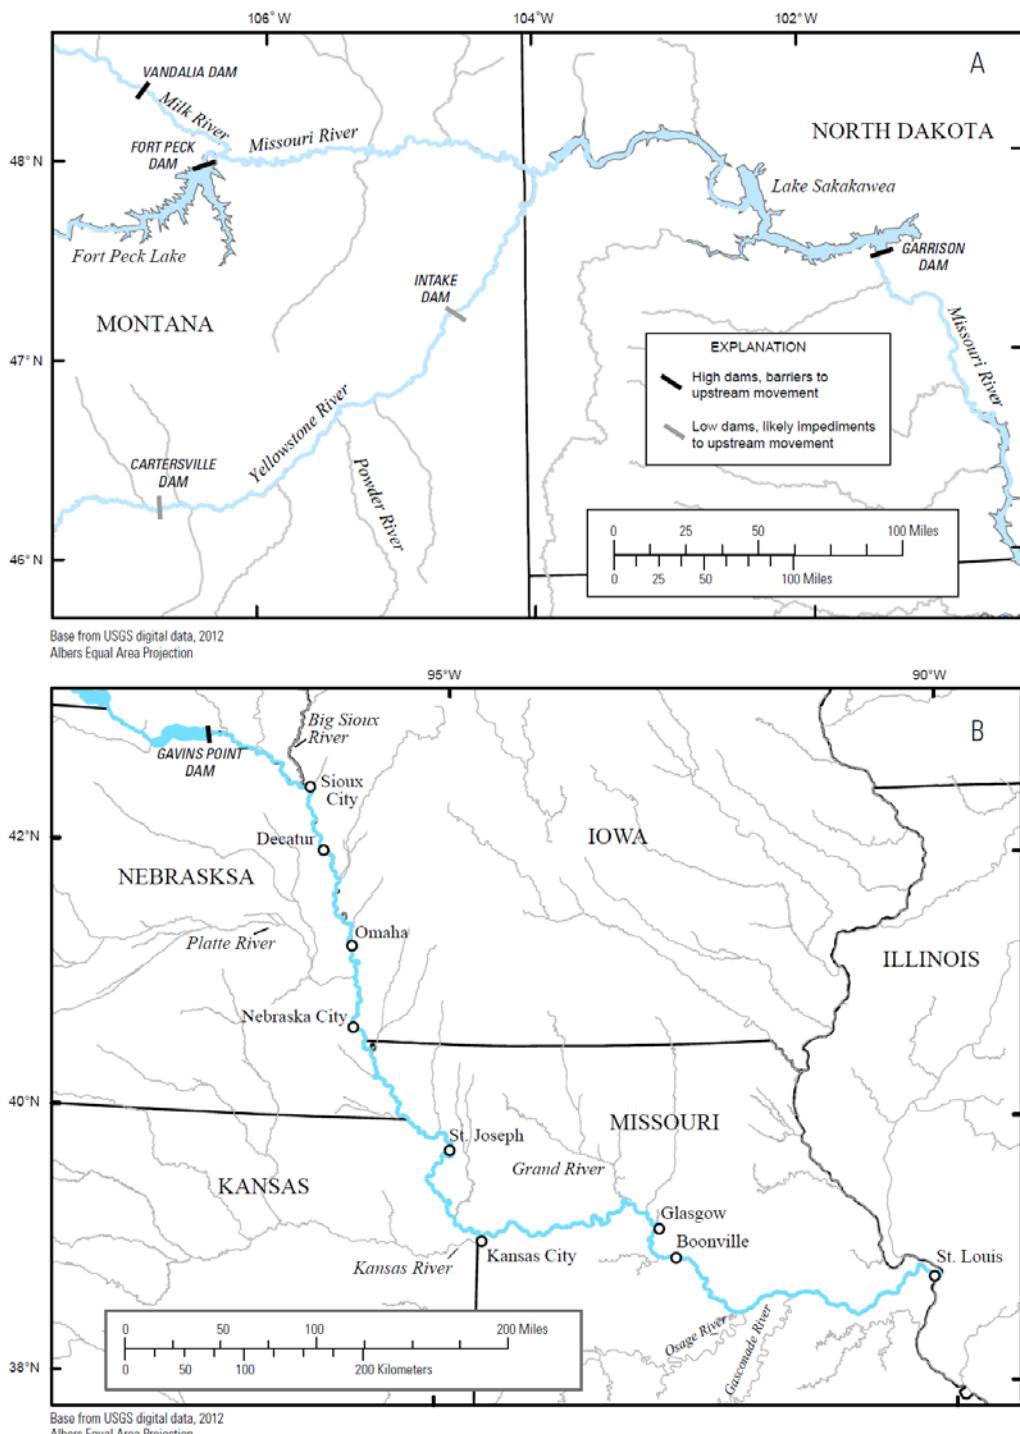

3 This geographic scope was constrained in part by the decision-making authority of the
 4 USACE and in part by present understanding of the geographic distribution of pallid
 5 sturgeon. Literature and ongoing research from outside this defined area was utilized
 6 where it helped to inform hypotheses evaluated in the EA. The reservoirs and inter-
 7 reservoir reaches (from Lake Sakakawea to Lewis and Clark Lake) were excluded from
 8 the effects analysis based on the assumption that these habitats are unlikely to support
 9 reproductive populations of pallid sturgeon. Figure 59 shows the area that is the main
 10 focus of research into potential management actions to recover the pallid sturgeon
 11 population in the Upper Missouri River.

12

13 Figure 58. Historical range and present-day occupancy of the pallid sturgeon and scope of the Missouri River
 14 included in the EA. Present day occupancy shown on the right side map includes the stretch of the river above
 15 Gavins Point Dam and below Fort Randall Dam, which is not included in the defined area of the Lower Missouri
 16 River. Pallid sturgeon may be found in reservoirs but do not prefer these habitats. Source: Figure 2 in Jacobson
 17 et al. 2016a

18

 4 **major tributaries, and reservoirs. Black lines are absolute barriers; gray lines are likely barriers, including run of**
 5 **river weirs.**

6 Management of Missouri River pallid sturgeon has historically occurred over four
 7 Recovery Priority Management Areas or RPMA's, and is now organized around four

1 Management Units (described in section D.1.3 of Appendix D, and Figure D.1). The area
2 upriver of Fort Peck Reservoir (former RPMA 1) is outside of the geographic scope of the
3 MRRP. The geographic scope of the MRRP (and this AM Plan) includes those portions
4 of the Missouri River encompassed by the portion of the Great Plains Management Unit
5 (GPMU) below Fort Peck Lake, the Central Lowlands Management Unit (CLMU), and
6 the portion of the Interior Highlands Management Unit (IHMU) above the confluence of
7 the Missouri and Mississippi Rivers (MRRMP-EIS, Section 1.8.1), corresponding to the
8 historic RPMA's 2-4 (Figure D.1). The USACE has jeopardy responsibilities for pallid
9 sturgeon under the ESA in these three RPMA's. The Yellowstone River is the only
10 tributary included in the geographic scope of the MRRP-EIS, due to its importance to
11 pallids in RPMA #2, and the effects of the Intake Dam. The Platte River has been
12 utilized by pallid sturgeon and information from the Platte River is relevant to an
13 understanding of pallid sturgeon populations in the Lower Missouri River, but the Platte
14 River is not within the geographic scope of the MRRP and the AM Plan. As occurred
15 during the EA, literature and ongoing research from outside the geographic area defined
16 for the MRRMP-EIS (e.g., upstream of Fort Peck Dam) may be utilized where it helps to
17 inform the evaluation of hypotheses and potential management actions.

18 **4.1.2 Key findings from Effects Analysis and more recent work**

19 **4.1.2.1 Purpose and methods of the EA**

20 The concept of an EA is rooted in the requirement within the ESA to evaluate the effects
21 of actions proposed by federal agencies on listed species or designated critical habitat,
22 using the best available science. Murphy and Weiland (2011) advocated for a rigorous
23 approach to EA that consists of three primary steps carried out once the problem has
24 been formulated with the definition of the proposed action, the area affected, and a
25 conceptual model of the physical and biological relationships relating actions to species
26 outcomes. The first step is to collect reliable scientific information, including
27 observations about the stressor and the range of stressor conditions and information on
28 population sizes and trends. The second step includes assessment of the data, including
29 using quantitative models to integrate existing information and identifying and
30 representing uncertainties. The third step is to analyze the effect of the actions on the
31 species to determine costs and benefits and identify alternatives.

32 This section summarizes the completed Phase 1 of the EA process and documented in
33 Jacobson et al. (2016a) and Fischenich (in review). The primary and relevant products
34 of the EA are summarized in the following reports and models:

- 35 • Summaries of existing data/information reflecting the state of science for the species
36 and their habitats to identify the effects of system operations and actions on species
37 populations and their habitats (Jacobson et al., 2015a)

- 1 • Conceptual Ecological Models (CEMs) to guide quantitative models (Jacobson et al.,
2 2015b)
- 3 • Hypotheses addressing critical uncertainties (Jacobson et al., 2016b)
- 4 • Quantitative models for forecasting the effect of different alternatives on species
5 performance. Modeled processes include reservoir operations and hydraulic
6 conditions (Fischenich, in review), habitat availability (Fischenich et al. 2014, in
7 revision), and species demographics (Appendix D of this Plan)

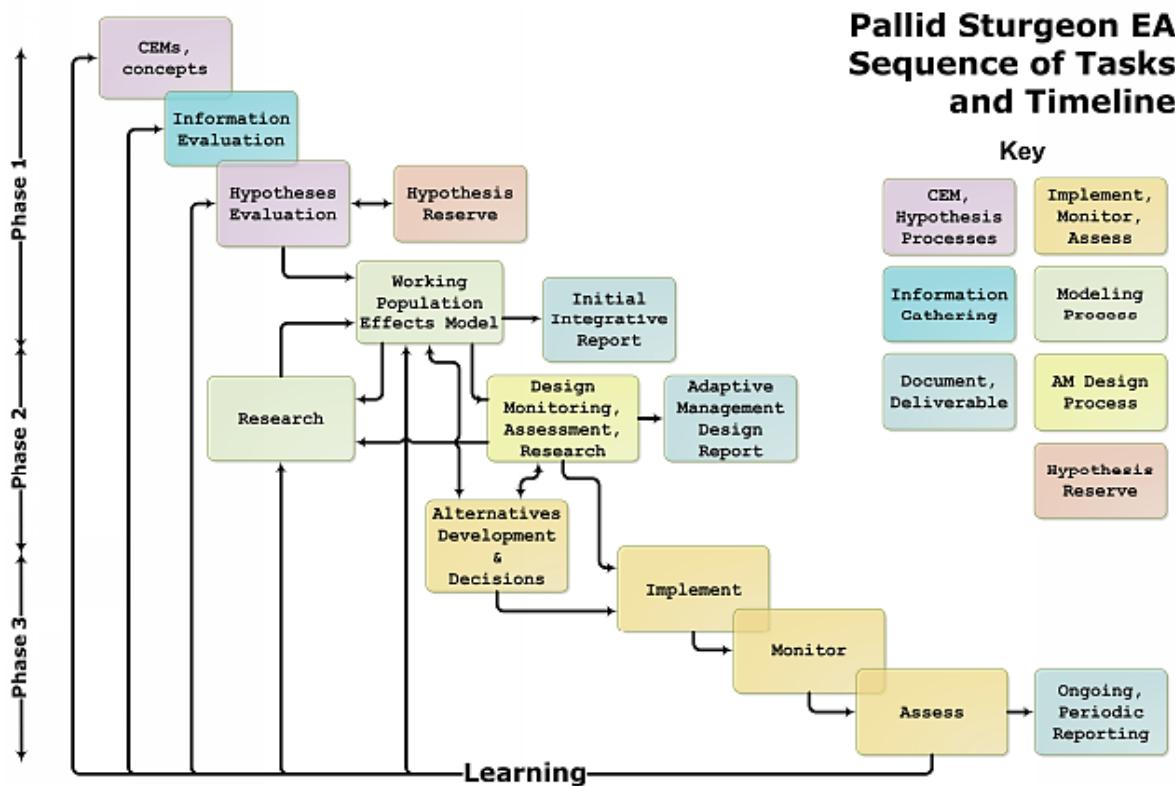

8
9 The EA provides an integrated assessment of the potential benefits of management
10 actions for pallid sturgeon in the Missouri River, and documents uncertainties in that
11 assessment. As the models presented in the EA are improved they will become focal
12 points for data assimilation, hypothesis generation, experimental design, and evaluation
13 of management actions. These models are intended to eventually be used to make
14 projections of habitat availability and population responses under different
15 combinations of actions, and to develop species/habitat targets under the MRRMP. The
16 EA is an on-going process that can be used to further refine strategies to address the
17 uncertainties and hypotheses identified as part of the EA. To date, this process has
18 involved the EA team, independent scientists on the ISAP and ISETR, as well as
19 representatives from MRRIC and its committees. The EA process can be used to address
20 various forms of “new information”, including both unexpected results derived from
21 science efforts within the AM program, as well as novel findings from outside the
22 program (see sections 2.5.4 and 6.2.5). Syntheses of new information could lead to
23 changes in existing hypotheses, the retrieval of hypotheses from the hypothesis reserve
24 (Figure 60) or the addition of new hypotheses.

25 4.1.2.2 *Overall conceptual model*

26 Conceptual ecological models (CEMs) illustrate population dynamics at the population
27 level, and show the linkage between management actions, ecological factors, and
28 biological responses (Jacobson et al. 2015b). The generalized population-level
29 conceptual model in Figure 61 was adapted from Figure 3 in Jacobson et al. 2015y. This
30 conceptual model demonstrates the conditions, processes, and potential management
31 actions that affect survival at critical life-stage transitions. In Figure 61, squares
32 represent different life-stages with arrows in the direction of development. Life-stage
33 transitions are influenced by the survival probability (diamonds) and the conditions,
34 processes, and management actions influencing survival (ovals and icons). The
35 conceptualized river in the middle of the graphic demonstrates the use of the river
36 mainstem or its tributaries during different life-stages (Wildhaber et al. 2007).

37

38

1

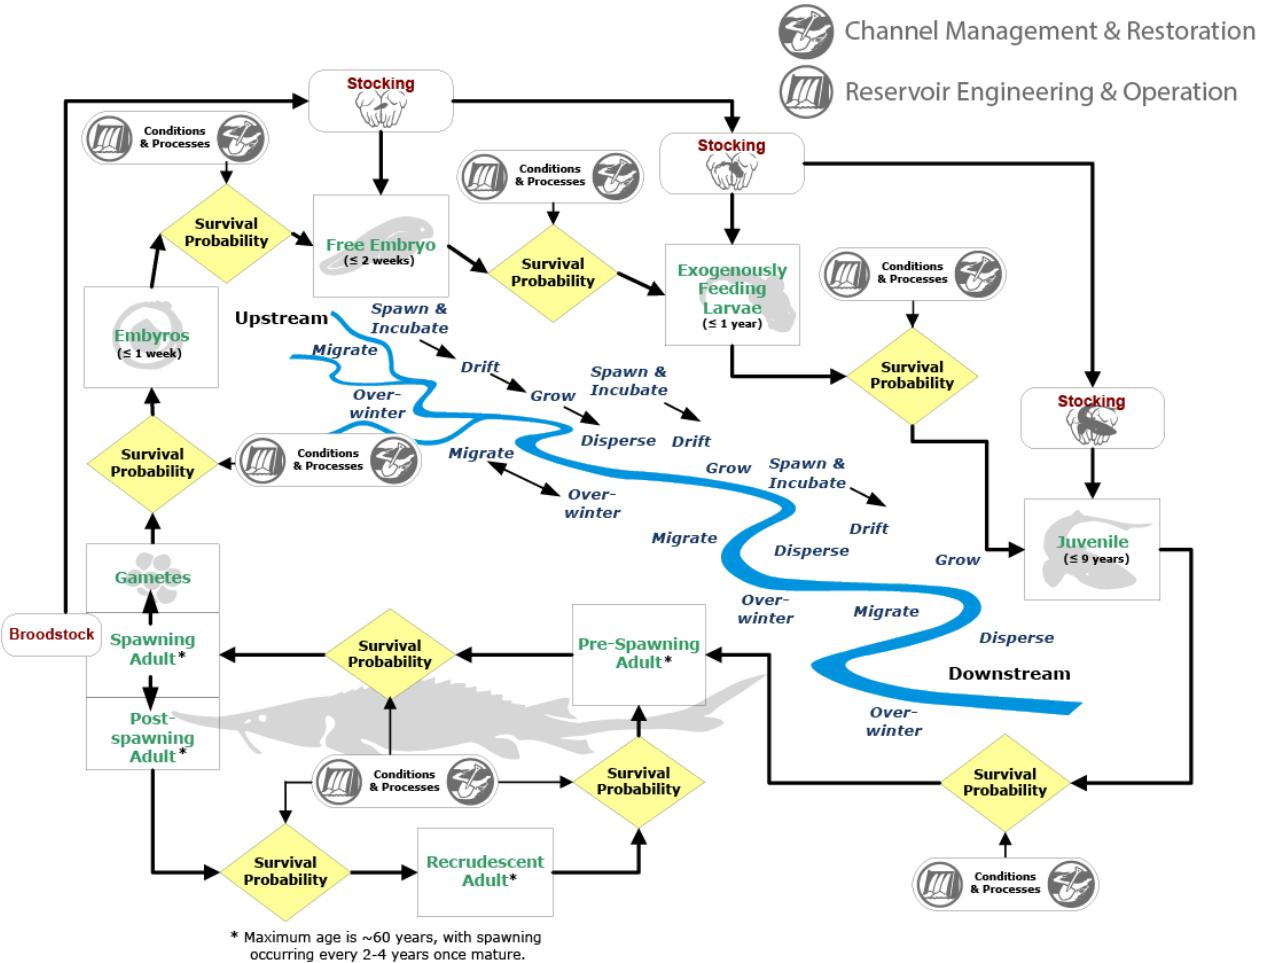

2 Figure 60. Phases 1, 2, and 3 envisioned for the EA process (Jacobson et al., 2016a).

3 The two classes of management actions represented in the figure are channel
 4 management and restoration, and reservoir engineering and operations. Channel
 5 management and restoration options include channel reconfiguration, interception and
 6 rearing complexes, spawning habitat creation, bank stabilization and in-river structures
 7 to alter velocities or flow paths. Reservoir engineering and operations include operating
 8 rules (e.g., flow pulses, drawdown), passage structures, and structures or actions to
 9 improve water quality (e.g., temperature, sediment, oxygen).

10

11 Life-stage component CEMs were developed by Jacobson et al. (2015b) to illustrate the
 12 driver-stressor relationships influencing survival of that life-stage transition. These life-
 13 stage transition survival probabilities correspond to the diamonds in Figure 61. Survival
 14 at each life history stage is a function of the conditions and processes which occur
 15 during that stage, which in turn are potentially affected by different management
 16 actions. Figure 61 also shows potential stocking activities (which historically have
 17 included stocking at free embryo, exogenously feeding larvae / fingerlings / younger

1 yearlings (all < 1 year old), and juveniles / older yearlings) and broodstock collection of
2 spawning adults.

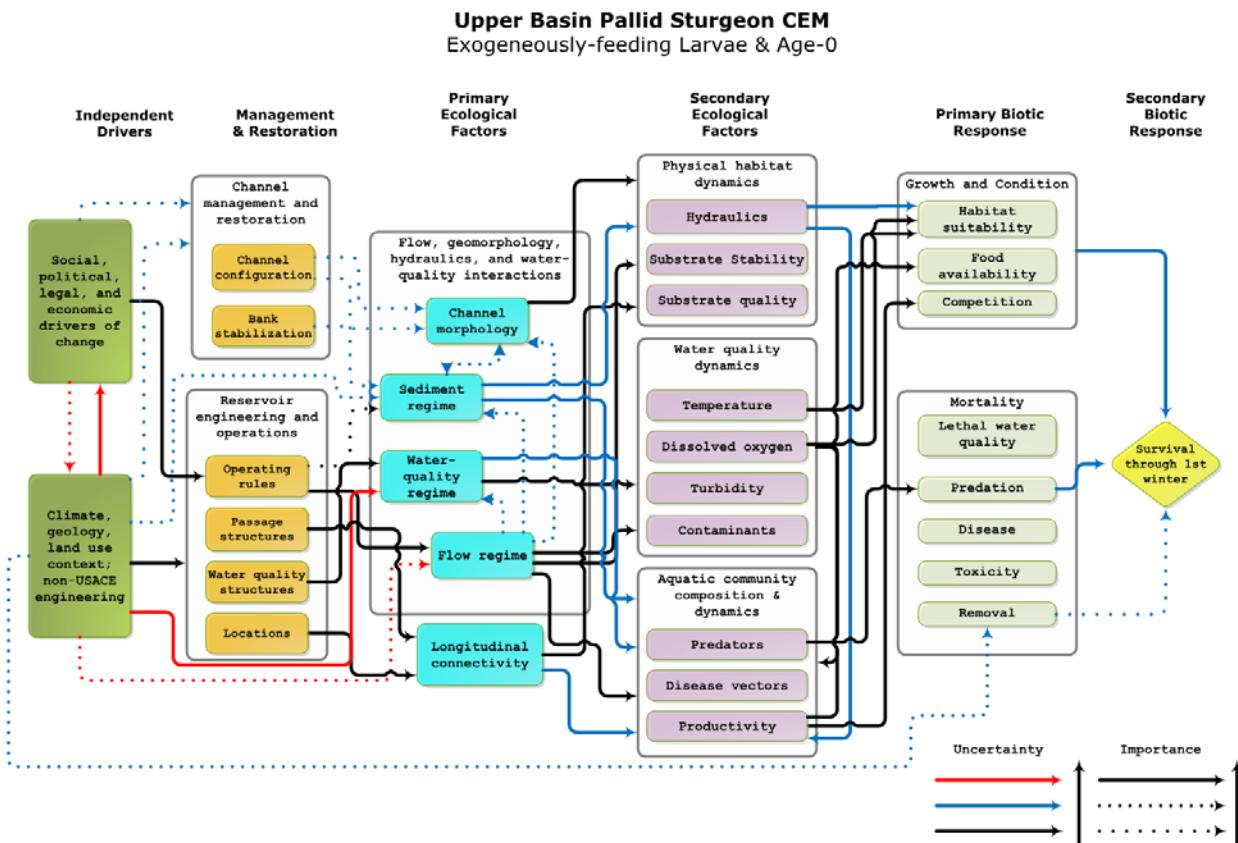

3

4 Figure 61. Generalized population-level CEM showing life stages, geographic context of pallid sturgeon
5 reproductive cycle. Fingerlings and yearlings less than 1 year old fit into the “exogenously feeding larvae” life
6 stage.

7 Figure 62 is an example of a life-stage component CEM. Each pair of columns, from left
8 to right can be considered a cause-effect linkage, with the final rightmost column being
9 the ultimate biotic response (Jacobson et al. 2015b). The classes of factors that were
10 considered include (from left to right in Figure 62): anthropogenic or geologic
11 independent drivers, management and restoration activities, primary ecological factors,
12 secondary ecological factors, primary biotic responses, and ultimately the secondary
13 biotic response of survival of that life-stage (yellow diamond). The conceptual model
14 uses a hierarchical structure of factors, whereby bounding boxes represent broad
15 descriptions of ecosystem factors and are common across all component CEMs, and the
16 colored boxes within each column are more specific factors which may vary depending
17 on the life-stage and location of the component CEM. Hypothetical relationships
18 between the factors were explicitly mapped out in a workshop process involving experts

1 in pallid sturgeon biology and Missouri River processes. Participants at these
 2 workshops characterized each relationship by its relative importance and uncertainty.
 3 The relative importance ranking used line weight used in Figure 62 (solid, dashed, and
 4 dotted lines, where solid represented the highest relative importance), and the
 5 uncertainty ranking used line color (black—least uncertainty, blue—moderate
 6 uncertainty, and red—most uncertainty). These hypothetical relationships provide the
 7 basis for the global hypotheses for the EA (Section 1.4.2).

8
 9 Figure 62. Example of a life-stage component CEM showing the cause-effect linkages leading to survival to the
 10 next life-stage (Jacobson et al. 2015b).

11 4.1.2.3 Collaborative population dynamics model

12 The collaborative pallid sturgeon population model (Jacobson et al. 2016a; Appendix D,
 13 section D.4.3) serves as a central tool to organize, assimilate, and evaluate information
 14 on Missouri River pallid sturgeon populations. The primary purpose of the model is to
 15 evaluate the population-level effect of management actions and provide metrics (e.g.,
 16 population viability, abundance) that link to fundamental objectives for pallid sturgeon.
 17 The description of the model presented here is a snapshot of the current state of the
 18 model, which has expanded in scope since the EA was developed. The models are the
 19 quantitative statement of hypotheses. Expressing hypotheses in a quantitative form

1 reveals where the most critical uncertainties exist in our understanding of functional
2 relationships (i.e., uncertainties in key inputs to decisions), which helps to prioritize
3 data collection and small-scale experiments. The models also provide a mechanism for
4 extrapolating observed changes at specific life-history stages (from field data) to their
5 long term population consequences, and propagating the inherent uncertainties in life-
6 stage specific survival probabilities (the diamonds in Figure 61). The structure of the
7 model mimics the structure of the revised population assessment program, as described
8 in Appendix D. This will provide benefits in both directions: essential empirical data for
9 model calibration, testing and application; and use of the model to design the most cost-
10 effective data collection procedures, explore alternative hypotheses, and evaluate the
11 long term consequences of current and proposed actions for fundamental and sub-
12 objectives.

13
14 The development of the stage-based collaborative model has several advantages over
15 previous age-structured models (e.g., Reynolds and Tyre 2011, Steffensen et al. 2013a,
16 Wildhaber et al. 2015. First, the collaborative model explicitly models all life-stages.
17 Specifically, there are several early life history stages that participants believed required
18 their own conceptual ecological models, including gametes, embryos, free embryos,
19 exogenously feeding larvae, and age-0 fish. The collaborative population model
20 faithfully represents the work of the participants who developed the component CEMs.
21 Second, the collaborative model has a flexible model structure template to model several
22 populations (i.e., upper river, lower river, and sub-populations if identified) at varying
23 spatial resolutions. Previous models were constrained to either the upper and lower
24 basins with most effort in the lower basin and a strong bias towards the lower basin
25 population (Jacobson et al. 2015b). Finally, the development of the collaborative model
26 occurred through a transparent process involving input from potential users using open-
27 source software with public-domain source code and open accessibility to an online
28 version. This tool will evolve and be modified to meet the AM process needs and the
29 community of scientists engaged in understanding pallid sturgeon population dynamics.

30 The geographic extent of the current model is limited to segments of the lower and
31 upper Missouri River (Figure 58). These two parts of the Missouri are subdivided into
32 bends representing the spatial grain of the population model. River bends are defined as
33 three continuous habitats (channel cross-over, inside bend, outside bend) and vary in
34 number and size from the lower to upper basin¹. Bends are used as a spatial
35 organization for the model, to accommodate movement of fish among bends in the
36 model, and because bends are the sampling units for the Pallid Sturgeon Population

¹ Lower: 317 bends, in river km, mean=4, min=0.2, max=19; in river mi mean=2.5, min=0.1, max=11.8;

Upper: 157 bends, in river km, mean=2.3, min=0.6, max=8; in river mi mean=1.4, min=0.4, max=5;

- 1 Assessment Program (PSPAP). The current temporal extent (duration of model runs) is
2 user defined and can be up to 50 years with a monthly time step.
- 3 The model requires basin-specific demographic rates and values (e.g., survival,
4 fecundity, sex ratio) and values for state variables (e.g., number of hatchery fish,
5 number of natural fish) to simulate population dynamics. Uncertainty is associated with
6 most of these inputs, though the number of stocked fish is known precisely. Inputs are
7 derived from literature and from experts within the basins. The population model is
8 initialized by drawing demographic values and rates from distributions. Next, state
9 values (i.e., number of hatchery or natural origin fish) are drawn from distributions. Age
10 structure is then initialized given the abundance and demographic rates drawn. For
11 example, if 4000 natural origin fish were stochastically selected, those fish are then
12 allocated to an age class given their cumulative probability of surviving, yielding the
13 typical exponential decay in number of fish with age. Model initialization makes an
14 assumption of population equilibrium as in past modeling studies (Steffensen et al.
15 2013), which basin experts agreed was reasonable. This assumption takes into account
16 the fact that, even in the absence of recruitment, population declines are expected to be
17 relatively small for a long-lived fish with high sub-adult and adult survival.
- 18 Current model implementation outputs the origin and fate of individual fish (i.e.,
19 natural, hatchery, mortality) for each time step over the years simulated. When multiple
20 stochastic replicates are simulated, values can then be post-processed to forecast values
21 like pseudo-extinction probabilities. Additional post-processing includes a function to
22 simulate a robust design capture-recapture program so that the model can be used to
23 inform population monitoring designs (discussed in section 4.4 and Appendix D).
- 24 The ultimate objective for the population model is to evaluate management actions
25 propagated through the pathways described in the CEMs. There are many gaps in
26 biological understanding linking primary and secondary biotic responses. Current
27 model implementation accepts demographic rates; however, direct effects of primary
28 biotic responses are uncertain or unknown. These uncertainties and unknowns aside,
29 the model framework development is focused at further development of the capacity to
30 evaluate primary biotic responses in two approaches. The first approach modifies the
31 demographic rate distributions as a function of a primary biotic response. For example,
32 the current model represents demographic rates in terms of a baseline survival rate, the
33 uncertainty in that survival rate, and potential changes in the survival rate as a function
34 of other factors (e.g., amount of food available for exogenously feeding larvae in
35 interception and rearing habitat). The mathematical form of these functions is described
36 in Appendix D, section B.4.3.3.

1 Sensitivity analyses of parameters in the collaborative population dynamics model
2 confirmed that early life-stage survival values were the most uncertain and have the
3 most leverage on population dynamics. Further, the EA team used the model to explore
4 how the persistence of pallid sturgeon in the Missouri River varied with different levels
5 of stocking. Parameter estimates generated from the modeling included estimates of
6 early life-stage survival rates needed to sustain a population under current stocking
7 rates. These numbers provide benchmarks to evaluate stocking and ongoing refinement
8 of survival rates. The early life-stage survival rates also represent a key parameter
9 uncertainty in the model (gamete, embryo, free embryo, exogenously feeding larvae,
10 age-0) because there are limited data on these probabilities. Another source of
11 uncertainty is the spatial dynamics including flow cues as a trigger for movement and
12 flow modifications for drift of free embryos. An additional complicating factor (not
13 included in the model) is hybridization between pallid sturgeon and shovelnose
14 sturgeon (Jacobson et al. 2016a), albeit hypothesized genetic consequences on
15 population demography are not well understood. The model's structure and proposed
16 applications are closely aligned with the proposed revisions to monitoring of pallid
17 sturgeon populations, as described in Appendix D.

18 4.1.2.4 *Initially modeled hypotheses and process for examining additional hypotheses*

19 The filtering approach used to determine the 21 hypotheses that were the focus of
20 conceptual and quantitative modeling (Upper River - Table 37, Lower River –Table 38)
21 was a stepwise process starting with the implicit hypotheses from the component CEMs.
22 A series of workshops were used to filter these hypotheses, link these hypotheses to
23 management actions, and determine if these actions were within the USACE authority
24 and jurisdiction (Jacobson et al. 2016b).

25 Jacobson et al. 2016b defined several categories of hypotheses (Table 1 in their report).
26 *Global* hypotheses are a set of possible, biologically important hypotheses, relevant to
27 population dynamics that are derived from the CEMs (see Appendix B). These implicit
28 hypotheses are depicted by the arrows between cells in the CEM. These were filtered by
29 the EA team to a set of 40 *candidate dominant* hypotheses that were identified by
30 experts as being important in pallid sturgeon population dynamics. Through a series of
31 workshops and a modified Delphi process, this list was filtered to 23 *working dominant*
32 hypotheses based on input from experts (Jacobson et al. 2016b). This list is meant to
33 include plausible, most biologically relevant hypotheses without regard to specific
34 management or mitigation actions. These working dominant hypotheses were then
35 linked to management actions resulting as many as 176 potential linkages, but when
36 consolidated across life-stages led to 53 hypotheses. The list was further reduced
37 through an expert survey to a list to 30 *working management* hypotheses. Finally, the
38 set of working management hypotheses was filtered by the USACE MRRP for actions

1 that were within the agency's authority and jurisdiction resulting in the 21 initially
2 modeled hypotheses selected for modeling in Phase 1 of the EA.

3 As learning occurs through the AM cycle, the list of hypotheses may expand and contract
4 beyond the initially modeled hypotheses. In anticipation of this, a hypotheses reserve
5 will explicitly manage the broad suite of hypotheses developed through the EA and
6 highlighted in the CEM. Using this concept, hypotheses can be brought forward or
7 moved back into reserve as information and understanding directs. The hypotheses
8 reserve concept includes: 1) hypotheses that are not deemed important to investigate at
9 this time; 2) have high uncertainty and require further investigation; and/or 3) are
10 outside USACE authority (see Jacobson et al. 2016b for examples).

11 The annual AM process described in Chapter 2 will bring forth new findings that lead to
12 adjustments, additions or rejections of the existing set of hypotheses. In addition, the
13 new information process (described in Section 2.5.4) provides a mechanism for bringing
14 forward new information that is analyzed by a technical team in a "joint fact finding"
15 process. This analysis could lead to hypotheses being brought forward from the list of
16 reserve hypotheses, or new action hypotheses being formulated, which would then be
17 included in the AM Plan, and further considered by the Technical Team and
18 Management Team.

19 The new information process is well illustrated by efforts currently underway for the
20 issue of declining fish condition, which involved the following steps:

- 21 • A problem with fish condition was observed by biologists with the Nebraska
22 Game and Parks Commission (NGPC) during efforts at broodstock collection in
23 the Lower Missouri River in the spring of 2015. NGPC biologists submitted an
24 issue paper to the USFWS and USACOE in January 2016.
- 25 • The NGPC evidence on this issue was then reviewed by the Chief of the
26 Threatened and Endangered Species Section of USACE and the Missouri River
27 Coordinator of the USFWS. They agreed that this issue merited further
28 investigation, and developed a charter (Bonneau and Kruse 2016) for a joint fact-
29 finding team (coordinated by the EA team for pallid sturgeon) to investigate the
30 fish condition issue. The charter for the investigation (Bonneau and Kruse 2016)
31 involves a detailed review of the evidence that pallid sturgeon are in poor or
32 declining condition (including patterns across space, time, size, age and wild vs.
33 hatchery fish), the potential for negative effects on reproduction and survival, the
34 likely causes of observed patterns that have potential impacts on reproduction
35 and survival, and the recommended next steps (including both science efforts and
36 potential remedial actions).

- 1 • A joint fact-finding team conducted a 6-month investigation into the problem,
2 following the terms of reference of the charter. The draft report of joint fact-
3 finding team (Randall et al. 2016) confirmed the existence of the pattern of
4 declining condition from 2012 to 2015, found variable levels of fish condition in
5 the same locations, and observed a higher percentage of fish in low condition
6 within the Lower Basin (particularly in the section of river between Omaha and
7 Kansas City). The draft report proposed various hypotheses to explain the
8 observed patterns, including reduced carrying capacity, changes in the amount of
9 suitable habitat following the 2011 flood, changes in prey base, intraspecific and
10 interspecific competition, and changes in fitness. Randall et al. (2016)
11 recommended a systematic evaluation of these alternative hypotheses in the AM
12 Plan through such activities as continued monitoring of movement and non-
13 lethal measures of fish health across contrasting regions and fish histories;
14 research on diet, bioenergetics, food webs and habitat changes to test alternative
15 hypotheses; necropsies of stored carcasses, and (possibly, following a reduction
16 in the number of possible hypotheses) carefully designed and monitored changes
17 in propagation strategies and/or other management actions.
- 18 • The ISAP reviewed the draft report of Randall et al. (2016), and made various
19 recommendations (webinar September 29, 2017), including applying different
20 methods of analysis to assess whether the apparent decline in condition might be
21 an artifact of an increasingly older population and the particular methods of
22 analysis that were employed in Randall et al. (2016).

23 • Subsequent work (R. Jacobson, USGS, presentation to MRRIC on November 15,
24 2016) used four different approaches to analyzing the data, and confirmed
25 declines in fish condition in the Lower Basin, but not in the Upper Basin.

26 • The draft report will be revised, subjected to internal and external peer review,
27 and published in 2017, first as a USGS technical report and later as a journal
28 paper, with all of the data and methods provided. The peer-reviewed
29 recommendations from the report will be considered for inclusion in the AM Plan
30 and annual work plan by the Fish Team and the Independent Science Program.

31 Beyond the 21 EA hypotheses, there may be additional factors affecting pallid sturgeon
32 recovery which will need to be considered in developing management actions and
33 experimental designs (e.g., fitness of pallid sturgeon, hybridization of pallid sturgeon
34 and shovelnose sturgeon; climate change (USFWS 2016)), but for which clear linkages
35 to USACE authority and jurisdiction are lacking. When developing designs for
36 management actions within USACE authority and jurisdiction, it is very important to
37 anticipate the influence of these additional factors on the potential effectiveness of

1 management actions, and the ability to evaluate action effectiveness. Genetics
2 information from field sampling will be informative on which genotypes appear to be
3 surviving better than others. Spawning habitats should be designed to reduce (not
4 increase) hybridization of pallid and shovelnose sturgeon. Trends in hybridization over
5 time should be tracked, so that they don't confound field and model based estimates of
6 the effects of various management actions. Finally, higher year to year variability in
7 flows due to climate change (USACE 2016) could create more variation in catch per unit
8 effort estimates of age 0 fish, making it more difficult to detect the effects of IRCSs. It is
9 vitally important for information on pallid sturgeon to be shared and communicated
10 (throughout their range, regardless of who collects these data), as data outside of the
11 scope of the MRRP may still have implications for actions within USACE authority and
12 jurisdiction (see section 6.3 Data Management).

13 *4.1.2.5 EA findings, critical uncertainties, potential actions and decision trees*

14 The key findings and potential routing for each of the initially modeled hypotheses are
15 summarized in Table 37 (Upper Missouri River) and Table 38 (Lower Missouri River).
16 Fundamental information gaps (high uncertainty) compromise the ability to quantify
17 many of the hypotheses of pallid sturgeon population dynamics. For some of the 21
18 hypotheses, the available information is from theoretical deduction, inferences from
19 sparse empirical datasets, or expert opinion. The degree of uncertainty and risk
20 associated with each hypothesis (risks to both pallid sturgeon and human
21 considerations) will guide the level and sequence of experimentation (i.e., Level 1 vs
22 Level 2, see Table 39). Hypotheses with the highest levels of uncertainty and risk will
23 first be explored through research, mesocosm experiments, opportunistic field
24 experiments or gradient studies. Specific management actions can be taken for
25 hypotheses with less uncertainty and risk, from limited implementation as field-scale
26 experiments (Level 2) to full field implementation (Level 3). This process of hypothesis
27 routing is further developed into Level 1, 2, and 3 actions in Section 4.2. Regardless of
28 the information gaps, key outputs from the EA were conceptual models and
29 hypothesized functional relationships that could help assess the effects of management
30 actions on pallid sturgeon life-stage survival.

31 The population model developed in the EA can be used to assess sensitivity of life-stage
32 specific demographic rates, assess some hypotheses related to stocking decisions, and
33 explore a limited number of management scenarios. However, information gaps prevent
34 linkage of flow and channel reconfiguration actions directly to population responses.

35 Aside from the population dynamics model described in Section 4.1.2.3, two other types
36 of models were developed for the EA to evaluate hypotheses. These included one-
37 dimensional advection/dispersion models to assess drift dynamics of free embryos
38 (Fischenich, in review), and 2-dimensional hydrodynamic models for functional habitat

1 assessments to provide an understanding of how the availability of functional habitat
 2 varies jointly with flow regime and channel reconfigurations. Models are available for
 3 both the upper and lower river. These models will be used to assess the effects of
 4 management actions on the survival of drifting free-embryos in the upper river, and for
 5 assessing the effects of flow and channel-reconfigurations on interception and habitat
 6 availability in the lower river.

7 **Table 37. Findings from Effects Analysis for Upper Missouri River hypotheses.**

Action Location	Action	Number	Management Hypothesis	Findings	Potential Routing
Upper Missouri River	Alter Flow Regime at Fort Peck	1	Naturalized flow releases at Fort Peck will result in increased productivity through increased hydrologic connections with low-lying land and flood plains in the spring, and decreased velocities and bioenergetic demands on exogenously feeding larvae and juveniles during low flows in summer and fall.	Theoretical support but inadequate data to model and forecast population response	Research on bioenergetics, hydrodynamic models, comparative field experiments
		2	Attractant flow releases at Fort Peck will result in increased reproductive success through increased aggregation and spawning success of adults.	Theoretical support, inference from other sturgeon species, but inadequate data to model and forecast population response	Research, monitor responses to events, possible pulsed flow experiment
		3	Reduction of main stem Missouri River flows from Fort Peck Dam during free-embryo dispersal will decrease main stem velocities and drift distance, thereby decreasing mortality by decreasing numbers of free embryos transported into headwaters of Lake Sakakawea.	Potential effective action, subject to contingent information	Research to resolve anoxia, use of Yellowstone, interstitial hiding, retarded drift
	Temperature Control, Fort Peck	4	Warmer flow releases at Fort Peck Dam will increase system productivity and food resource availability, thereby increasing growth and condition of exogenously feeding larvae and juveniles.	Theoretical support but inadequate data to model and forecast.	Research on bioenergetics, hydrodynamic models, comparative field experiment
		5	Warmer flow releases from Fort Peck Dam will increase growth rates, shorten drift distance, and decrease mortality by decreasing free embryos transported into headwaters of Lake Sakakawea.	Potential effective action, subject to	Research to resolve anoxia, use of Yellowstone, interstitial

				contingent information	hiding, retarded drift
	Sediment Augmentation , Fort Peck	6	Installing sediment bypass at Fort Peck will increase and naturalize turbidity levels, resulting in decreased predation on embryos, free embryos, and exogenously feeding larvae.	Theoretical support, but laboratory data equivocal; no specific models	Research on predation of eggs, embryos, free embryos
Yellowstone River	Passage at Intake	7	Fish passage at Intake Diversion Dam on the Yellowstone River will allow access to additional functional spawning sites, increasing spawning success and effective drift distance, and decreasing downstream mortality of free embryos and exogenously feeding larvae.	Potential effective action, subject to contingent information	Implementation underway. Complement with robust monitoring and evaluation
Upper Missouri and Yellowstone	Upper Basin Propagation	8	Stocking at optimal size classes and in optimal numbers will increase growth rates and survival of exogenously feeding larvae and juveniles.	Potential effective action, subject to hatchery capacities	Implemented, validate with monitoring, assessment. Research on optimization
		9	Stocking with appropriate parentage and genetic diversity will result in increased survival of embryos, free embryos, exogenously feeding larvae, and juveniles.	Theoretical support, no specific data, models to forecast for pallids	Research on linking parentage and population viability
Lake Sakakawea	Drawdown, Lake Sakakawea	10	Drawdown of Lake Sakakawea will increase effective drift distance, decreasing downstream mortality of free embryos and exogenously feeding larvae.	Potential effective action, subject to contingent information.	Research to resolve anoxia, use of Yellowstone, interstitial hiding, retarded drift

1

Table 38. Findings from Effects Analysis for Lower Missouri River hypotheses.

Action Location	Action	Number	Management Hypothesis	Findings	Potential Routing
Lower Missouri River	Alter Flow Regime at Gavins Point	11	Spring flow pulses from Gavins Point will provide aggregation and spawning cues for reproductive pallid sturgeon, resulting in increased spawning success.	Theoretical support, inference from other sturgeon species, but inadequate data to model and forecast population response	Research, monitor responses to events, possible pulsed flow experiment
		12	Naturalized flows from Gavins Point dam will increase productivity and food availability for age-0 pallid sturgeon through improved connectivity with channel-margin habitats and low-lying floodplain lands, increased primary and secondary production, and increased growth, condition, and survival of exogenously feeding larvae and juveniles.	Theoretical support, inference from hydrodynamic models, but data inadequate to model, forecast population response	Research on bioenergetics, comparative field experiments, possible pulse flow experiment.
		13	Naturalized flows from Gavins Point Dam will decrease energetic requirements of age-0 pallid sturgeon through decreased velocities, resulting in increased growth, condition, and survival for exogenously feeding larvae and juveniles.	Theoretical support, inference from hydrodynamic models, but data inadequate to model, forecast population response	Research on bioenergetics, comparative field experiments, possible pulse flow experiment.
		14	Decreased flows in late May and June from Gavins Point Dam will result in decreased velocities and dispersal distance, resulting in increased survival of pallid sturgeon free embryos.	Theoretical support, inference from hydrodynamic models, but data are equivocal as limiting factor and population response	Research into drift dynamics
	Temperature management, Gavins Point	15	Increased temperatures in May from Gavins Point will provide aggregation and spawning cues for reproductive pallid sturgeon.	Theoretical support, inference from other sturgeon species, data equivocal about magnitude of change, population response	Research, monitor responses to events
Lower Missouri River	Channel Reconfiguration	16	Channel reconfiguration to increase quality and availability of spawning habitat will increase successful	Theoretical support, support from sturgeon species,	Research in spawning dynamics, comparative

Action Location	Action	Number	Management Hypothesis	Findings	Potential Routing
			fertilization, incubation, and hatch of pallid sturgeon.	hydrodynamic models, but data are equivocal as limiting factor and population response	field experiment
		17	Channel reconfiguration to increase food-producing habitats will increase growth and survival of age-0 pallid sturgeon, through increased channel complexity and improved bioenergetic conditions to increase prey density (invertebrates and native prey fish).	Theoretical support, inference from hydrodynamic models, but data are equivocal as limiting factor and population response	Implemented in part, comparative field experiment, validate with monitoring, assessment
		18	Channel reconfiguration to increase availability and quality of foraging habitat will increase survival of age-0 pallid sturgeon, through increased channel complexity and minimized bioenergetic requirements for resting and foraging.	Theoretical support, inference from hydrodynamic models, but data are equivocal as limiting factor and population response	Implemented in part, comparative field experiment, validate with monitoring, assessment
		19	Reconfiguration of the channel to promote interception of drifting free embryos from the thalweg and transport to supportive channel-marginal habitats will increase survival of free embryos to exogenously feeding age-0.	Theoretical support, inference from hydrodynamic models, but data are equivocal as limiting factor and population response	Possibly implemented in part, validate with monitoring, assessment, comparative field experiments
		20	Improved stocking strategies by optimizing stocked size classes will improve age-0 to age-1 survival of hatchery-origin pallid sturgeon.	Potential effective action, subject to hatchery capacities.	Implemented, validate with monitoring, assessment. Research on optimization
Propagation Lower Basin		21	Improved stocking strategies by optimizing genetic diversity will improve population viability for pallid sturgeon.	Theoretical support, no specific data, models to forecast population response	Implemented, validate with monitoring, assessment. Research on linking parentage and population viability

1 Potential management actions were also identified and include flow management,
2 temperature management, sediment augmentation, passage at Intake Dam,
3 propagation, stocking, and the construction of interception and rearing complexes
4 (IRCs), spawning habitat, and food and foraging habitat. These actions were selected
5 using a scientific filter (do they benefit the species?), a human considerations filter (are
6 impacts acceptable?), and a feasibility filter (can actions be feasibly implemented?).
7 Further filtering of management actions occurred through the MRRMP process, as
8 described in Chapter 2 of the DEIS).

9 Key outcomes and uncertainties from the EA can be conceptualized in a decision tree
10 framework that highlights the possible management actions or additional hypotheses
11 and monitoring (Jacobson et al. 2016a), which can assist the *evaluate* and *decide* stages
12 of the AM process (Sections 4.5 and 4.6 of this plan). Decision trees are shown below for
13 the Upper Missouri and Yellowstone rivers (Figure 63) and for the Lower Missouri River
14 (Figure 64). The decision trees illustrated in Figure 63 and Figure 64 follow the same
15 format and graphical representation. Key uncertainties related to a subset of the key
16 hypotheses being evaluated in the AM Plan are depicted by yellow diamonds and
17 potential actions are depicted by blue boxes. The initial uncertainty, posed as a question,
18 is listed in the top-left corner. The yes/no answer to this question is connected by
19 arrows which either lead to another uncertainty (question) or a potential action. The
20 directionality of subsequent decisions follows the life-stages in sequence, which would
21 be the most systematic approach to understanding recruitment failure. Useful
22 information can be generated outside of the sequence as well. For example, using age-0
23 shovelnose sturgeon as a surrogate species may generate insights about food limitations
24 of pallid sturgeon and allow for an emphasis on other hypotheses. Appendix F contains
25 decision trees with added detail and explanation, which accommodate all of the
26 hypotheses considered in the EA, as well as recent advances in understanding. These
27 detailed decision trees are an important input to the prioritization of Level 1 and Level 2
28 science activities (Table 39), also described in Appendix F.

29 The Upper Missouri-Yellowstone rivers decision tree (Figure 63) focuses on hypotheses
30 related to drift and dispersal. The effects of fragmentation are clearest, and the available
31 drift/dispersal distance and hypothesized inhospitable headwaters of Lake Sakakawea
32 pose a distinct constraint on recruitment. The ability to overcome these constraints has
33 bearings on the efficacy of potential management actions including flow management,
34 temperature management, and drawdown of Lake Sakakawea at Garrison Dam. The
35 first uncertainty is whether sediments in the headwaters of Lake Sakakawea are anoxic
36 and lethal to developing embryos. If this is confirmed, then the next uncertainties are
37 whether pallid sturgeon are able to migrate and spawn in the Yellowstone River and
38 whether spawning occurs >500 km upstream (an approximation of required drift
39 distance). If pallid sturgeon do not migrate a sufficient distance up the Yellowstone

1 River, then the uncertainty is whether retarded drift (interstitial hiding and other
2 mechanisms) occurs. If it occurs, then potential actions include flow management
3 (attractant flows for adults, low flows to slow rate of movement of embryos),
4 temperature management (increased temperature to increase development rates), and
5 drawdown of Lake Sakakawea (or other, as yet unidentified, means of addressing the
6 anoxia). If pallid sturgeon choose to spawn primarily in the lower Yellowstone River
7 then recruitment failure appears likely, as there is not sufficient drift distance before
8 Lake Sakakawea. If pallid sturgeon migrate to the Yellowstone River but do not spawn at
9 a distance far enough upstream from Lake Sakakawea, the uncertainty is again whether
10 retarded drift (interstitial hiding) occurs. The potential action is drawdown of Lake
11 Sakakawea (or otherwise addressing anoxic headwater conditions). Finally, if pallid
12 sturgeon are attracted to migrate up the Yellowstone River, are able to pass Intake
13 Diversion Dam in sufficient numbers, and are attracted to migrate and spawn far
14 enough upstream in the Yellowstone River watershed, potential recruitment may occur
15 and other management actions may be unnecessary. The level of drawdown of Lake
16 Sakakawea contemplated in Figure 63 has not been determined. It would need to be
17 sufficient to provide a biological benefit in terms of drift distance, while still being
18 consistent with authorized purposes. A much larger drawdown of Lake Sakakawea
19 would provide greater drift distance but would not be consistent with current
20 operations. Taking advantage of natural variations in water conditions (e.g., a series of
21 low water years in which reservoir levels naturally decline) could be very informative for
22 determining the survival of free embryos under conditions with greater drift distance.

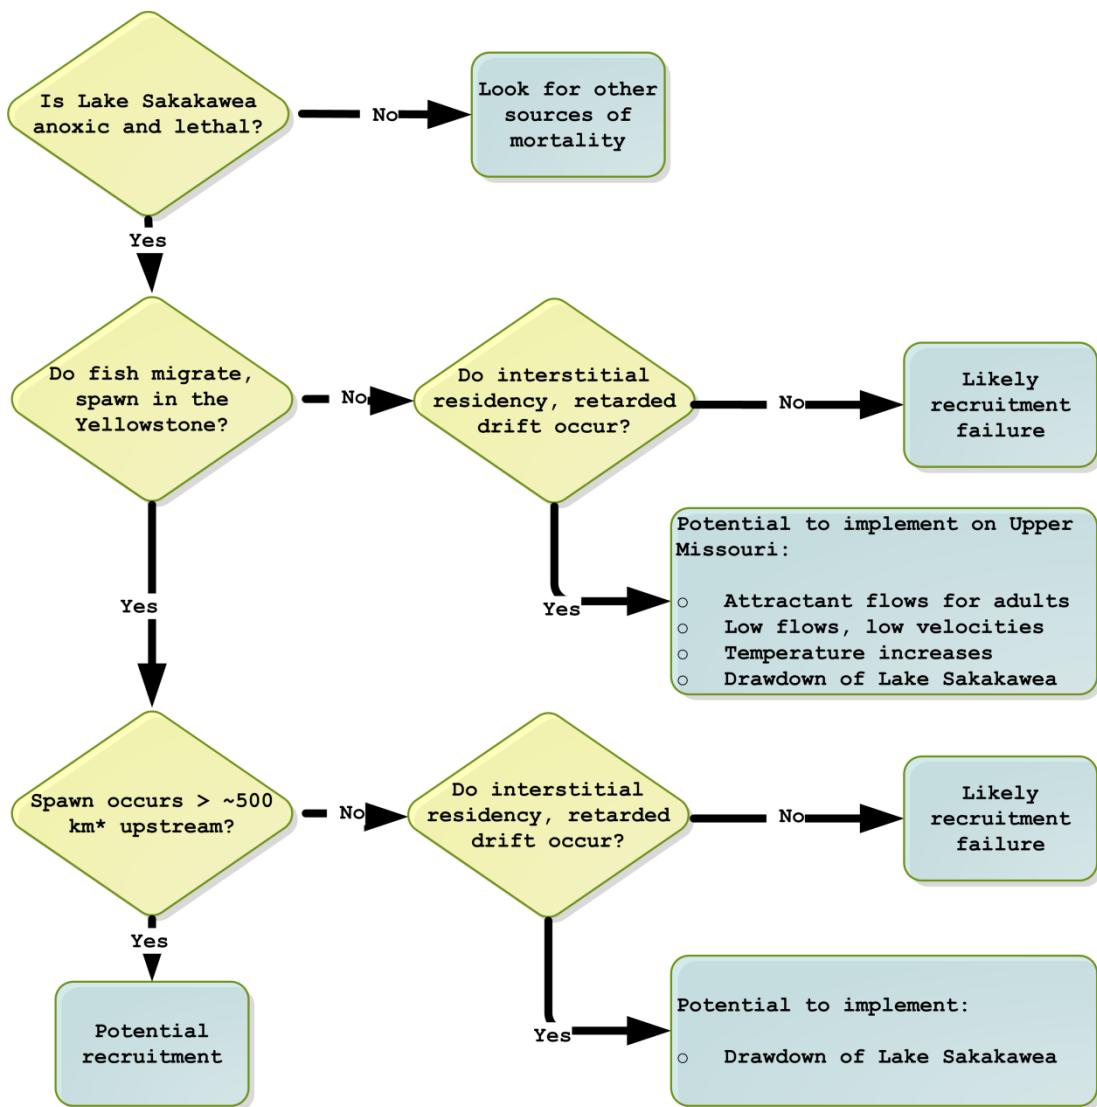

23 Figure 63 shows a complex set of alternative future scenarios. Focusing research studies
24 and AM experiments on key decision nodes (i.e., the diamonds in Figure 63) can
25 simplify the decision process by rejecting some hypotheses and thereby eliminating
26 certain branches on the decision tree. Such advances help to clarify that some actions
27 are very unlikely to be successful, which helps to focus management attention on the
28 remaining actions with potential benefit, and reduces the number of possible future
29 scenarios. Learning is not instantaneous. Various forms of variability (e.g., year to year
30 variations in flows, temperatures and reproductive spawners; spatial and temporal
31 variability in the distribution of free embryos within each year) require multiple years of
32 observations to separate the signal from the noise, and draw reliable conclusions.
33 Therefore, though information from pallid sturgeon studies will be analyzed and
34 reported annually, major decisions on actions are likely to proceed based on several
35 years of accumulated and carefully confirmed findings.

36 Interstitial hiding was a hypothesis that emerged through the expert opinion process.
37 Prior to the summer of 2015, immediate drift was also never observed directly in pallid
38 sturgeon; immediate drift was inferred but not documented. USGS studies have
39 provided good evidence regarding drift rates, and further studies are planned (Patrick J.

1 Braaten, USGS, pers. comm.). Emerging evidence suggests that pallid and shovelnose
2 embryos are not retained within the substrate, in contrast to lake sturgeon (Delonay et
3 al. 2015 conference presentation). However, these results have not yet been peer
4 reviewed and published. Until these USGS studies have been peer reviewed and
5 published, the interstitial hiding hypothesis is retained in the AM Plan, given somewhat
6 less emphasis, and enhanced with the idea of retarded drift to encompass myriad other
7 factors that could also affect net dispersal rates. Passage at Intake will result in
8 approximately 400 km of drift (less than the rough guideline of 500 km in Figure 63), so
9 the degree of retarded drift is important. These issues are discussed further in section
10 4.2.5.2 with respect to Intake Dam.

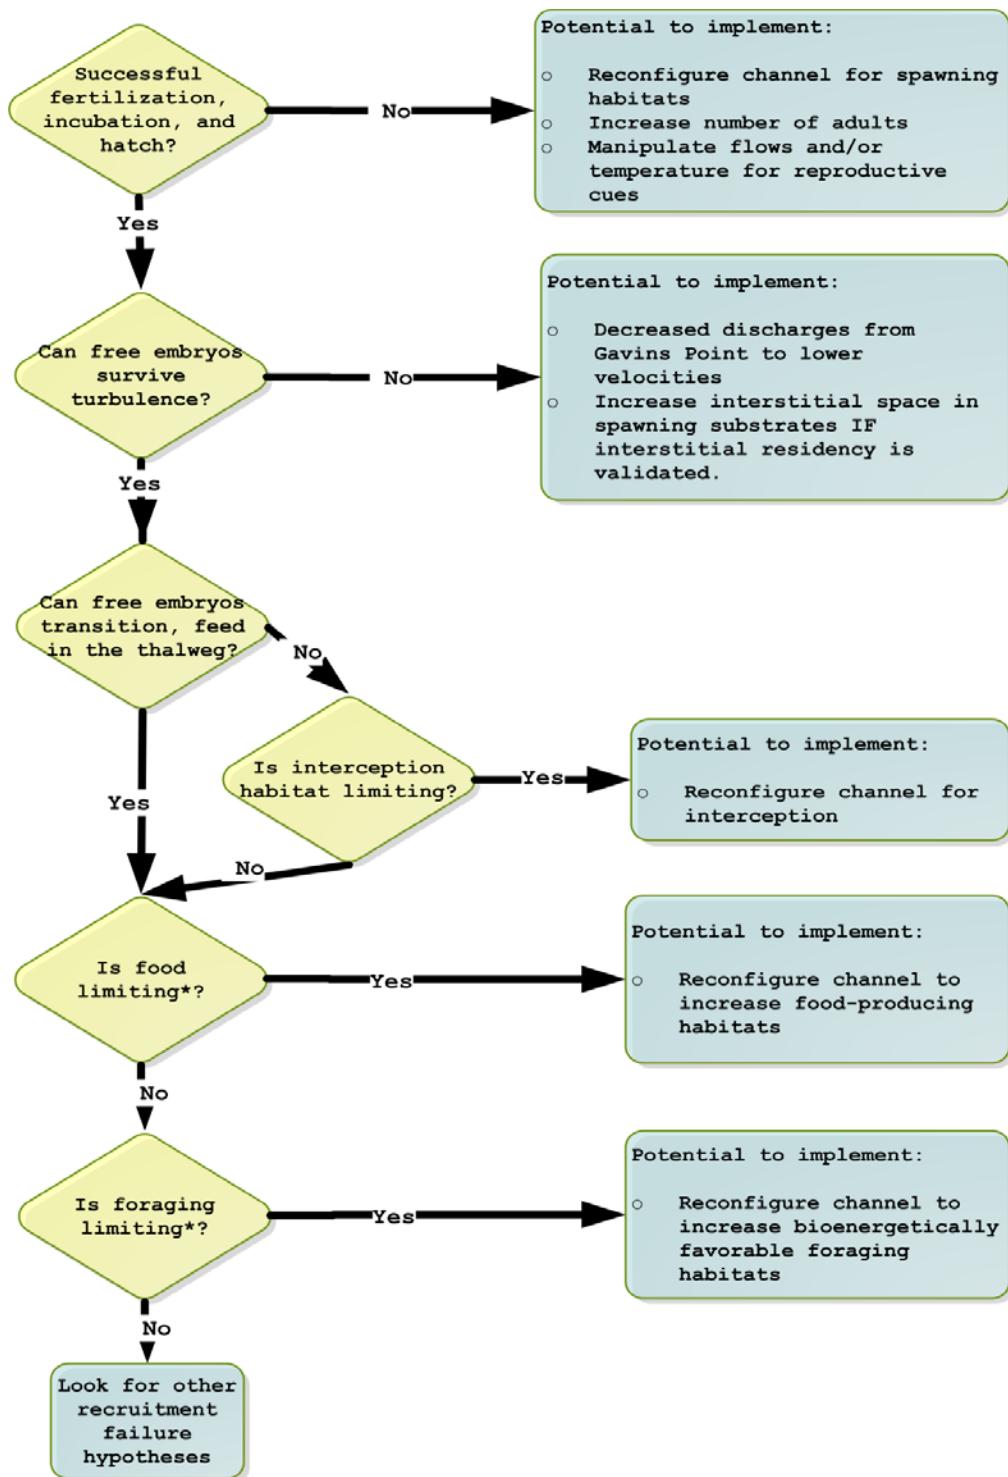

11 In June and July 2016, a large group of collaborating agencies and scientists conducted
12 the Missouri River Pallid Sturgeon Free Embryo Drift Study, which is described here:
13 <https://www2.usgs.gov/blogs/csrp/>. The study involved dye-studies to test assumptions
14 in hydraulic models, the release of nearly 700,000 free embryos 2 miles downstream of
15 the Milk River, and detailed monitoring of the movement and dispersal of these free
16 embryos, guided by advection-dispersion models that were recalibrated based on the
17 dye studies. The results of this experiment will yield insights on the proportion of free
18 embryos that are able to find suitable rearing habitat and avoid the anoxic zones at the
19 upper end of Lake Sakakawea, and provide improved tools for predicting the rate of
20 movement and dispersion of both water and free embryos. This information is critical to
21 determining the required dispersal distance for free embryos, and addressing key
22 decision nodes in Figure 63.

23

* 500 km distance upstream is a coarse guideline because it would provide about 9 days for drift and development under purely passive drift assumptions.

Figure 63. Diagram of a decision tree for addressing contingent information for drift and dispersal related management actions in the Upper Missouri and Yellowstone rivers. In this diagram, drawdown of Lake Sakakawea (lower right) is to a level consistent with authorized purposes. The diamond in the upper left refers to the headwaters of Lake Sakakawea. Information exists to partially answer some of the questions in the diamonds, as discussed in the text. A more detailed decision tree, including other actions such as augmentation, is contained in Appendix F (Figure F2). Source: Jacobson et al. 2016a.

* Note that a habitat type may be limiting at one point in time and not at another. For example, food-producing habitat may not be limiting at low population numbers but may become limiting as population size increases.

1 For the Lower Missouri River decision tree (Figure 64), uncertainties center around how
2 pallid sturgeon use the Lower Missouri River, tributaries, and the Mississippi River.
3 This has bearing on the efficacy of potential management actions including flow and
4 temperature management (Gavins Point Dam); manipulating spawning substrates to
5 increase aggregation, reduce hybridization and improve reproductive success; , and
6 channel reconfiguration to construct foraging and food habitat and interception and
7 rearing complexes. The first uncertainty is whether fertilization, incubation, and hatch
8 can be demonstrated. If this cannot be established, potential actions include flow and
9 temperature management from Gavins Point Dam for reproductive cues, channel
10 reconfiguration for spawning habitat, and increased stocking to generate more adults. If
11 successful fertilization, incubation, and hatch can be demonstrated, then the next
12 uncertainty is whether velocities and turbulence are lethal to drifting free embryos. If
13 velocities and turbulence are lethal to drifting free embryos, then potential actions are
14 flow management (decreased discharge), and manipulating spawning substrates to
15 allow greater access of free embryos to interstitial spaces. If free embryos can survive
16 turbulence, then the next uncertainty is whether free embryos being transported in the
17 thalweg will starve unless they can settle into supportive, channel-margin habitats, or if
18 instead they can transition to first feeding, find food, and grow to the point where they
19 are mobile enough to seek habitats on their own. If free embryos cannot transition or
20 settle into supportive habitats, IRCs could be constructed. If IRCs are not limiting, and
21 free embryos can transition or feed in the thalweg, the uncertainty is whether food is
22 limiting. If food is not limiting, then other recruitment failure hypotheses need to be
23 considered. If food is limiting, foraging and food habitat could be achieved through
24 channel reconfiguration. Completing science studies in parallel rather than in sequence
25 can accelerate the learning process about the different diamonds in each decision tree.

4.2 Plan and Design

4.2.1 Pallid sturgeon framework

27 On November 2, 2015, the USFWS provided the USACE with a Planning Aid Letter
28 (USFWS 2015a) confirming support for a document called “Lower Missouri River Pallid
29 Sturgeon Framework, Targets and Decision Criteria” (USFWS and USACE 2015). This
30 document provides guidance for actions to be included in the Missouri River Recovery
31 Management Plan Environmental Impact Statement (MRRMP-EIS), and its structure
32 has been used to guide the section of this AM Plan dealing with actions to be
33 implemented in the Lower Missouri River (section 4.2.6). Though an equivalent
34 document has not yet been generated for the Upper Missouri River, we have applied a
35 similar structure to discussions of actions to be implemented in the Upper Missouri
36 River (section 4.2.5). Chapter 2 of the MRRMP-EIS provides guidance on the rationale
37 for including some actions in the alternatives to be analyzed (for both the Upper and
38 Lower Missouri River), while excluding others.

1 Since the AMP is intended to provide the means of evaluating the effectiveness of
2 actions described in the MRRMP-EIS, and the Pallid Sturgeon Framework (USFWS and
3 USACE 2015) describes those actions, the Framework is a foundational document. Key
4 principles underpinning the Framework are as follows (extracted from USFWS and
5 USACE 2015):

- 6 • Given the lingering uncertainties regarding the scope and scale of the management
7 actions necessary for the USACE to avoid jeopardizing the continued existence of
8 pallid sturgeon, a strategy reliant upon a progressive AM program is the most
9 effective way to manage risks to the pallid sturgeon.
- 10 • The Framework is expected to accelerate the identification of recruitment
11 bottlenecks, resulting in a more strategic and focused implementation of appropriate
12 management actions. This approach has the added benefit of minimizing impacts to
13 stakeholders and avoiding unnecessary implementation costs.
- 14 • The artificial propagation program would be continued throughout the Framework's
15 implementation as guided by the USFWS Basin-wide Stocking and Augmentation
16 Plan, and improvements to that program related to genetic concerns, disease,
17 stocking size, etc., would be pursued consistent with that plan.
- 18 • Implementation of management actions at Level 3 (described below) for each
19 hypothesis would be required within a specified timeframe, provided the hypotheses
20 associated with the action are not rejected by that time.
- 21 • At any time during the Framework's implementation, it may become apparent that:
22 1) a particular action is not needed, 2) a proposed action requires modification to be
23 effective, or 3) that some new action not previously evaluated is required.

24 4.2.1.1 *The four levels of the framework*

25 The Framework consists of four levels of activity, as described in Table 39: research
26 (Level 1); in-river testing (Level 2); scaled implementation (Level 3); and
27 implementation at the ultimate scale required (Level 4). The lower river refers to the
28 mainstem Missouri River downstream of Gavins Point Dam, including the influences (to
29 the extent they are relevant) of upstream reservoirs like Fort Randall and Lewis and
30 Clark Lake, influences of major tributaries, and some portion of the Middle Mississippi
31 River. While originally developed for the Lower Missouri, the concepts are equally
32 applicable to the Upper Missouri.

33 As information is developed from Level 1 and 2 studies or through monitoring of
34 effectiveness of management actions, the Framework's decision criteria will be used to
35 determine when and what action should follow. Decisions might include:

- 36 a) accepting that the scientific information supports the hypothesized action and:

- 1 1. moving to the next most important science question pending for each big
 2 question; or:
 3 2. moving to implementation of higher-level (i.e. Level 2, 3 or 4) actions;
 4 b) determining that the scientific information does not support the hypothesized action
 5 and:
 6 1. refining the hypothesis and continuing scientific investigations; or
 7 2. rejecting the hypothesis and promoting an alternative hypothesis that better
 8 explains observed information.
 9 c) to begin implementing at Level 3 because a time limit for a hypothesized action has
 10 been reached and results remain equivocal (studies at Levels 1 and 2 might continue
 11 concurrently)

12 **Table 39. Pallid sturgeon framework for the lower Missouri River (same as Table 6)**

Level 1: Research	Population Level Biological Response <u>IS NOT</u> Expected	Studies without changes to the system (Laboratory studies or field studies under ambient conditions)
Level 2: In-river Testing		Implementation of actions at a level sufficient to expect a measurable biological, behavioral, or physiological response in pallid sturgeon, surrogate species, or related habitat response.
Level 3: Scaled Implementation	Population Level Biological Response <u>IS</u> Expected	In terms of reproduction, numbers, or distribution, initial implementation should occur at a level sufficient to expect a meaningful population response progressing to implementation at levels which result in improvements in the population. The range of actions within this level is not expected to achieve full success (i.e. Level 4).
Level 4: Ultimate Required Scale of Implementation		Implementation to the ultimate level required to remove as a limiting factor.

13
 14 Level 1 and 2 studies are directly tied to those uncertainties and management
 15 hypotheses highlighted in the EA that, if resolved, could significantly affect the
 16 implementation of management actions. They can continue concurrently with Level 3
 17 efforts (to better understand cause-effect mechanisms), but are generally intended to
 18 inform future actions at Level 3. Although Level 2 studies have learning as a primary
 19 objective, they can also provide measurable and meaningful benefits to pallid sturgeon
 20 populations and, in such cases, would be counted toward targets in the same manner as
 21 Level 3 actions. Criteria for accepting or rejecting specific hypotheses, for assessing the
 22 results of scaled experiments, and for moving from Level 1 to Level 2 or Level 2 to Level
 23 3 actions are described in section 4.2.4.

1 Chapter 2 of the MRRMP-EIS provides the rationale for which actions are currently
2 included or excluded from Level 3 implementation in the EIS. Actions excluded from
3 Level 3 implementation may still be the focus of investigations at Levels 1 and 2.

4 *4.2.1.2 Current status of actions, relative priority of Level 1 investigations, and overview of*
5 *decision criteria*

6 Table 40 shows the current status of actions under consideration for both the Upper and
7 Lower Missouri River, in terms of the 4-level framework in Table 39, based on the EA,
8 the MRRMP-EIS and the Lower Missouri River Framework. In addition, Table 40 shows
9 the relative priority of Level 1 investigations. As illustrated in Figure 41 and discussed in
10 section 3.2.1 (Bird Framework), an action may change in scope, be removed from
11 consideration, or be added as a potential action even though it was not part of the EIS or
12 part of the Selected Alternative (with the required review processes).

13 Figure 65 provides an overview of the decision criteria for moving actions from Level 1
14 through Levels 2, 3 and 4, as well as for abandoning or revising certain actions. Decision
15 criteria guide the Technical and Implementation Teams when evaluating monitoring
16 and other information and in developing recommendations for consideration by the
17 agencies. Appendix C provides a detailed listing of all Level 1 and 2 science components
18 and associated decision criteria. For those science components prioritized for the first
19 five years after the ROD, decision criteria are summarized in Table 43 for the Upper
20 Missouri and Table 44 for the Lower Missouri.

21 The descriptions of experimental designs for L3 actions in Section 4.2.5 (Upper
22 Missouri) and Section 4.2.6 (Lower Missouri) are examples based on the current
23 understanding of which actions may be included in the MRRMP-EIS. It is possible that
24 actions at Levels 2 to 4, which are not currently included in the MRRMP-EIS, are
25 currently planned for investigation at Level 1. Investigations at Level 1, if favorable,
26 might ultimately lead to implementation at implementation of actions at Level 2 or
27 Level 3. If such Level 2 or Level 3 actions are determined to be outside the scope of the
28 alternative selected in the ROD then a supplemental NEPA process would be required
29 before implementation (section 2.2.5).

30

31

1 Table 40 Current status of actions under consideration for both the Upper and Lower Missouri River, and
 2 relative priority of investigations at each level.¹ Details of the formulation of alternatives and the rationale for
 3 decisions on these alternatives will be included with the release of the Draft EIS in December 2016.

Action location	Action	Current level of implementation and relative priority			Comments
		Level 1	Level 2	Level 3	
Upper Missouri River	Alter Flow Regime at Fort Peck	Low	Depends on results of Level 1		Continue to investigate biological benefits with better information on interstitial residency and movement rates of embryos at Level 1. Not currently included in Preferred Alternative, but one possible outcome of research studies and AM experiments (see Figure 63).
	Temperature Control, Fort Peck	Low	Depends on results of Level 1		Continue to investigate biological benefits at Level 1. Not currently included in Preferred Alternative, but one possible outcome of research studies and AM experiments (see Figure 63).
	Sediment Augmentation at Fort Peck	Low	Depends on results of Level 1		Continue to investigate at Level 1. Not currently included in Preferred Alternative.
Yellowstone River	Passage at Intake	High	High	High	This action and associated evaluations of effectiveness have been determined to be a high priority by the USFWS in coordination with the USACE and Reclamation for the Upper Missouri ² .
Upper Missouri and Yellowstone	Upper Basin Propagation	High	High	High	The Recovery Team and participating federal agencies are considering several potential changes to the propagation program, including the number, age and genetics of stocked fish, and stocking locations. The new information analysis of the fish condition (section 4.1.2.5) may lead to additional EA hypotheses concerning propagation. The experimental designs described in section 4.2.5.1 of the AM Plan are applicable to multiple potential action hypotheses. Included in Preferred Alternative. Amount of augmentation could be decreased significantly in the next Basin-wide Stocking and Augmentation Plan

¹ Detailed alternative formulation and decision rationale will be included with the release of the Draft EIS in December 2016

² For further information please see the Final EIS and ROD for the Lower Yellowstone Intake Diversion Dam Fish Passage Project (USBOR and USACE 2016a, 2016b)

Action location	Action	Current level of implementation and relative priority			Comments
		Level 1	Level 2	Level 3	
Lake Sakakawea	Drawdown, Lake Sakakawea	Low	Depends on results of Level 1		Continue to investigate biological benefits with better information on interstitial residency and movement rates of embryos at Level 1. Not currently included in Preferred Alternative, but one possible outcome of research studies and AM experiments (see Figure 63).
Lower Missouri River	Alter Flow Regime at Gavins Point	Medium-High	Medium-High after 9-year period post-ROD, depending on results of Level 1 studies	Medium-High after 9-year period post-ROD, depending on results of Level 1 and Level 2 studies	Spawning cue flows will be a high priority Level 1 investigation. Naturalization of the flow regime at Gavins Point will be a medium priority Level 1 investigation. Not currently included in Preferred Alternative, but might be implemented as a test flow following 9 years of study post-ROD (see Figure 64 and section 4.2.6.6).
	Temperature management, Fort Randall	Low	Depends on results of Level 1		Not currently included in Preferred Alternative, but one possible outcome of research studies and AM experiments (see Figure 64).
	Channel Reconfiguration	High	High	High	Construction of habitat to support early life history survival (e.g., Interception and Rearing Complexes, Spawning Habitats) is included in the Lower Missouri Framework. Included in Preferred Alternative.
	Propagation Lower Basin	High	High	High	As described above for the Upper Missouri River. The experimental designs described in section 4.2.6.1 of the AM Plan are applicable to multiple potential action hypotheses. Included in Preferred Alternative.

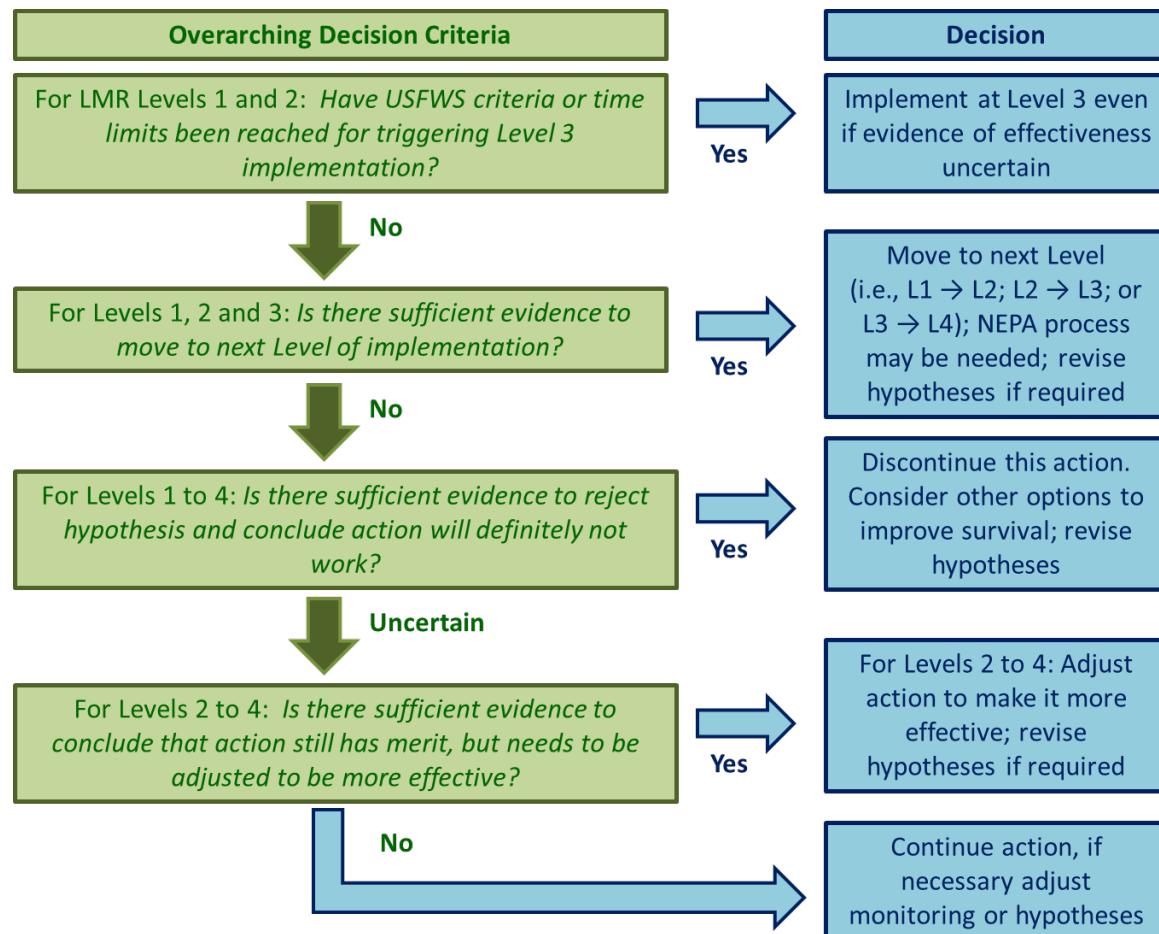

Figure 65 Overview of the decision criteria for various decisions in the Pallid sturgeon framework. The top green box refers to the decision criteria in Table 41 and Table 42. The remaining green boxes refer to the evidence and decision criteria in Appendix C, Table 43, Table 44 and Table 53. The blue box second from the bottom (“Discontinue this action, consider other options to improve survival”) is illustrated by the decision trees in Figure 63 and Figure 64

7 4.2.1.3 Level 3 Actions, Targets and Decision Criteria:

8 Requirements for Level 3 were developed collaboratively by the USACE and USFWS and
 9 reflect both best available science and policy considerations. Implementation of
 10 management actions at Level 3 for any limiting factor would commence at the earlier of
 11 two triggers (to allow quick response to information): 1) within two years of affirmative
 12 results from Level 1 and/or 2 studies indicating an action is needed for a limiting factor
 13 (see decision criteria in section 4.2.4 and Appendix C), or 2) the established time limits
 14 in Table 42 have been reached, and the results of studies/tests at Levels 1 and 2 of the
 15 associated hypotheses still remain equivocal.

16 There is a tradeoff between taking action and decreasing uncertainty. To help find an
 17 appropriate balance, USFWS and USACE (2015) defined a series of five questions as a
 18 proposed checklist to guide decisions to advance to implementation at Level 3 for any of

1 the hypotheses identified by the EA (Table 41). Work at Level 1 will help to answer
 2 questions 1, 2, 3 and 5. The decision criteria described in Appendix C (and summarized
 3 in Table 43 and Table 44 for components prioritized for the first five years post-ROD)
 4 will help in deciding whether or not to move hypotheses from Level 1 to Level 2. Level 2
 5 in-river tests of actions will be particularly helpful for providing empirical evidence to
 6 address question 4; strong experimental designs will be required to provide compelling
 7 evidence. If all five questions can be answered "Yes", advancement to Level 3
 8 implementation would be triggered. If an affirmative answer to four of the five questions
 9 exists and either question 1 or question 2 is equivocal, implementation of Level 3
 10 management actions would be triggered within two years (unless the hypothesis is
 11 rejected in that timeframe). It may be possible to answer question 2 (e.g., the amount of
 12 spawning, feeding or rearing habitat required for age-0 fish) without knowing which of
 13 these factors are most limiting recruitment to age-1. In this chapter we provide a more
 14 detailed hierarchy of questions to evaluate the effectiveness of Level 2 and Level 3
 15 actions, which are summarized in sections 4.5 (Evaluate) and 4.6 (Decide).

16 **Table 41.** Supplemental lines of evidence strategy for triggering Level 3 implementation. See above text.

	Question	Y	U	N
1	Is this factor limiting pallid sturgeon reproductive and/or recruitment success?			
2	Are pallid sturgeon needs sufficiently understood with respect to this limiting factor?			
3	Do one or more management action(s) exist that could, in theory, address these needs?			
4	Has it been demonstrated that at least one kind of management action has a sufficient probability of satisfying the biological need?			
5	Have other biological, legal, and socioeconomic considerations been sufficiently addressed to determine whether or how to implement management actions to Level 3?			
Criteria for Level 3 implementation				
1 - A "Yes" to all five questions triggers Level 3 implementation				
2 - A "Yes" to four of five, with an "Uncertain" for either #1 or #2 triggers a two-year clock to either reject the hypothesis or implement at Level 3				

1 The USFWS and USACE (2015) defined time limits for implementation of Level 3
 2 actions and their scope, expressed as targets (Table 42). These time limits are intended
 3 as a determination to proceed if the evidence for or against particular actions remains
 4 equivocal (i.e., a decision could be made to either abandon or proceed with actions at
 5 Level 3 prior to these time limits). The targets for IRCs were subsequently revised by the
 6 USFWS (2016). The time limits were set by the USFWS based on a recognition of the
 7 tradeoff between two objectives: 1) learning what actions are likely to be effective (which
 8 requires more time for Level 1 work); and 2) the need to take actions to benefit the
 9 species even if uncertainty remains about the effectiveness of such actions. As
 10 knowledge is gained from Level 1, 2 and 3 actions, the timeframe for implementation
 11 may be adjusted, targets may be changed, management actions may be refined, and
 12 hypotheses may be dismissed. The “rules” by which these decisions will be made are
 13 outlined in the decision criteria for the respective management hypotheses, subject to
 14 the overarching governance and decision process laid out in Chapter 2 of this AM Plan.

15 **Table 42. Summary of time limits for implementation and scope of actions.**

Action Category	Time Limit*	Minimum Scope	Maximum Scope
Population augmentation (Level 3)	Immediate	Current stocking rate as directed by USFWS Basin-wide Stocking and Augmentation Plan	Variable over time as directed by USFWS Basin-wide Stocking and Augmentation Plan
IRC habitat development (Levels 2 to 4)	Stage 1: study phase (years 1-3 post-ROD)	Build 2 IRC sites per year (paired with control sites), adding 33,000 ac-d/yr of suitable habitat, using staircase design ¹ . Assess potential for refurbishing existing SWH sites as IRCs	
	Stage 2 – continue study phase (years 4-6 post-ROD)	Build 2 IRC sites per year (paired with control sites), adding 33,000 ac-d/yr ¹ of suitable habitat. Refurbish SWH sites in addition to study sites (rate TBD).	
	Stage 3 - Level 3 implementation (years 7-10 post-ROD)	Continue assessing IRC sites and refurbishing new SWH sites, adding at least 66,000 ac-d/yr ¹ of suitable habitat. Determine required rate of Level 3 implementation based on stages 1 and 2.	
	Stage 4 – Level 4 implementation	Remove IRC habitat limitations to pallid sturgeon survival by implementation at Level 4.	
Spawning habitat ² (Level 2)	2 years	1 spawning site	See decision tree in Figure 78
Spawning cue flows (Level 2)	9 years	Requirement for spawning cue flows (and appropriate scope) depends on the outcome of Level 1 monitoring and modeling studies during years 1-9. ³

Notes to Table 42

1. Units of ac-dy/year are calculated based on how the flow regime and channel configuration result in cumulative days of availability of suitable habitat during the growing season. Progression through each stage of IRC habitat development is contingent on outcomes and hypothesis tests (USFWS 2016); efforts could be halted if evidence shows IRCs are not successful. Experimental design for IRC sites is described in section 4.2.6.3 and Appendix E. Refurbishment of SWH sites into IRCs is described in section 4.2.6.4.

1 2. Anticipated as a Level 2 pilot projects focused on developing and evaluating high-quality spawning habitat.
2 Spawning habitat implementation will be guided by the decision tree in section 4.2.6.3 (Figure 78). The evaluation of
3 spawning areas will be based on comparing attraction, egg survival, and hatch to existing spawning areas (see section
4 4.2.6.5).

5 3. See evidentiary framework in Table 48, section 4.2.6.6. Bird impacts and status, reservoir levels, and HC impacts
6 will inform decisions regarding spawning cue flows below Gavins Point Dam in any particular year.

7

8 **4.2.2 Tradeoffs between different learning strategies**

9 As noted in the previous section, there is a tradeoff between taking action and
10 decreasing uncertainty. Taking actions at Level 3 or 4 without strong evidence of their
11 effectiveness may be costly, and may use resources which could have been better
12 allocated. On the other hand, there are constraints on how much can be learned from
13 retrospective studies of past data, analyses of the current system, laboratory
14 experiments and mesocosm experiments. Delaying Level 3 or 4 actions that have
15 potential benefits could delay the recovery of pallid sturgeon. The AM strategy needs to
16 find the appropriate balance between three risks: 1) premature implementation of
17 ineffective actions, which wastes resources; 2) excessive delay in implementing actions
18 which would have helped the population; and 3) implementation of multiple concurrent
19 actions without an ability to determine which actions are most effective, which makes
20 future management adjustments more difficult.

21 The AM Plan embodies a fast pace of learning, by implementing many nondependent
22 Level 1 components concurrently or nearly concurrently rather than sequentially (as
23 explained in Appendix C). Too many concurrent activities could however be
24 overwhelming and inefficient. Therefore, the AM Plan also prioritizes some components
25 to be implemented during the first five years post-ROD, and defers others for
26 consideration beyond this period (as explained in Appendix F). Concurrent
27 implementation of multiple components will require a substantial investment in early
28 and carefully planned research. Level 1 science components jointly provide
29 complementary lines of evidence that cumulatively affect decisions to implement field
30 experiments at Level 2.

31 **4.2.3 Recommended learning strategy for AM Plan**

32 In developing a learning strategy for the AMP, we have adopted the following principles:

- 33 • Wherever possible conduct L1 research concurrently to accelerate learning,
34 consistent with the criteria for prioritization described in Appendix F.
35 • Combine all lines of evidence from L1 research to determine level of support for and
36 form of design of L2 experimental management actions.
37 • Use L2 actions to test action effectiveness and to develop experimental designs that
38 would be applicable at both L2 and L3;

- 1 • For L3 actions already underway (e.g., propagation) use L1 and L2 actions to confirm
2 that these actions are working as intended, to better understand cause and effect,
3 and to determine if L3 actions need to be adjusted.
- 4 • In evaluating L2 actions and associated hypotheses, seek to maximize spatial and
5 temporal contrasts within the constraints of both feasibility and authorized
6 purposes, so as to develop the clearest possible inferences from L2 actions.
- 7 • Design L1 and L2 research to efficiently transition to Level 3 based on learning,
8 rather than exceeding time limits.
- 9 • Ensure that Level 2 experiments do not risk negative effects on either pallid sturgeon
10 or human considerations.

11 **4.2.4 Overview of Level 1 and 2 Components and Decision Criteria**

12 Table 4 and Table 5 list the 12 big questions and 21 associated hypotheses for pallid
13 sturgeon. For each big question, science components have been developed for Level 1
14 and Level 2 (see definitions in Table 39). Appendix C of this document provides a
15 detailed explanation of each study component, while this section provides a tabular
16 overview of those activities prioritized for the first five years after the ROD (see
17 Appendix F for further details on the prioritization criteria that were used). Study
18 components are classified as:

- 19 • **Engineering/technology:** studies needed to a) develop technology to measure
20 pallid sturgeon responses to a management action (for example, new telemetry
21 technology, new population modeling approaches) or b) develop engineering
22 approaches to achieving the management action (for example, engineering designs
23 capable of increasing interception of drifting free embryos).
- 24 • **Biological screening:** studies to screen a management hypothesis and better
25 determine the magnitude of potential benefit of a management action. For example,
26 biological screening could describe a study to determine whether growth or survival
27 of age-0 pallid sturgeon is food limited. If so, studies would proceed to quantify
28 functional relations between the management action and the population response; if
29 not, the management hypothesis might be placed in reserve until the biological
30 relevance was established.
- 31 • **Level of biological effect:** studies to quantify the functional relationship between
32 levels of management action and biological response, for example, to determine how
33 much survival increases for an increment of increased food-producing habitat. The
34 functional relations that come from understanding levels of biological effect are
35 critical to modeling and projecting the effects of management actions on the species.

36 In addition, biological-screening and biological-effect studies are classified by approach.
37 Because the sturgeon life cycle is complex and critical parts of it involve very small fish
38 in a fast, deep and turbid river, improvements in scientific understanding are likely to

1 require a combination of approaches. Approaches range from laboratory studies, which
2 provide highly controlled, but unrealistic conditions, to field-gradient studies, which
3 typically lack experimental controls and replication, but take place under realistic
4 conditions.

- 5 • **Laboratory experiment** – controlled experiment at laboratory scale, typically
6 involving randomization and replication for statistical rigor. Includes experiments to
7 determine fundamental biological rates – for example, embryo development rate as a
8 function of temperature – and behavioral experiments like drift studies in racetrack
9 flumes.
- 10 • **Mesocosm experiment** – experiments outside of the strict controls of
11 laboratories, but at less than field scale. Examples include experiments in controlled
12 stream or pond environments. These conditions are incrementally closer to field
13 conditions compared to laboratory experiments, but lack the full dynamism of the
14 field example and typically involve somewhat less statistical rigor and precision of
15 measurements compared to laboratory experiments.
- 16 • **Field-gradient experiment** - using existing gradients of hydrologic, geomorphic,
17 and biotic conditions to identify and/or quantify biological effects. These
18 experiments often substitute space for time, or for treatment level. They take
19 advantage of existing conditions and offer to provide results under realistic
20 conditions, but often lack replication and statistical rigor. Gradient studies require
21 care to reduce or eliminate interacting variates.
- 22 • **Monitoring/assessment** – as used in this document, monitoring/assessment
23 denotes data collection of physical and/or biological data, but not necessarily in a
24 hypothesis-testing or adaptive-management framework (field experiments – next
25 category – include hypothesis-driven monitoring/assessment in an AM framework).
26 Monitoring often provides critical contextual or covariate information, for example
27 water quality or discharge, or population indices or metrics.
- 28 • **Modeling** – numerical experiments with computational models to test sensitivity of
29 habitats or population dynamics to changing parameter values and to explore system
30 dynamics. An example is using a well-calibrated population model to test population
31 responses to variable stocking levels.
- 32 • **Field experiment** – manipulative field experiment to quantify responses to
33 management actions and to test hypotheses. Examples would be pulsed-flow
34 experiments to elucidate effects of spawning cues, or controlled experiments on
35 varied channel reconfigurations to document effects on foraging habitat availability.
36 Although these are planned experiments, they fit the definition of “quasi-
37 experiment” because they typically lack randomization, replication, and/or
38 independence of treatments.

1 Appendix C provides a detailed description of all Level 1 and 2 science components, as
 2 well as the decision criteria for evaluating their outcomes. Table 43 and Table 44 (for the
 3 Upper Missouri and Lower Missouri, respectively) provide a summary of the Level 1 and
 4 2 components that are prioritized for the first five years after the ROD, based on the
 5 preferred alternative in the MRRP-EIS, and the prioritization process described in
 6 Appendix F. These tables summarize the metrics to be obtained by the work within each
 7 component, the criteria to be applied in decisions regarding progress to the subsequent
 8 component or level of investigation, and the degree of confidence in these decisions
 9 given the metrics to be provided by each component and the complexity of the
 10 component study. These tables are based on current understanding of research needs,
 11 and will need to be periodically revised, including after the ROD.

12 Table 43. Overview of highest priority Level 1 and 2 science components for the Upper Missouri, anticipated to
 13 be completed within the first five years of the Record of Decision (ROD) (subject to budget and resource
 14 constraints). Appendix C contains a complete list of all Level 1 and 2 components, and Appendix F describes
 15 the prioritization process. Components listed in Appendix C but not in this table could be implemented beyond
 16 the 5-year, post-ROD period. Metrics and decision criteria with associated degrees of certainty for the working
 17 management hypotheses are summarized from Appendix C. Categories for Degree of Certainty: 1 = Definitive,
 18 2 = Statistically rigorous, 3 = Indicative but not authoritative, 4 = Expert judgment of multiple lines of evidence
 19 required. BQ = Big Question, L = Level, C = Component (e.g., BQ1/L1/C2 is Big Question 1, Level 1,
 20 Component 2). Work under BQ6 subject to Recovery Team discussions and Propagation Strategy. Hypotheses
 21 are from Table 1 in Jacobson et al. 2016a.

Question, Level and Study Components	Key Metrics	Simplified IF - THEN Decision Criteria	Degree of Certainty *	Concurrent / Dependent Components
Big Question 1 – Spawning Cues: Can spring pulsed flows from Fort Peck synchronize reproductive fish, increase chances of reproduction and recruitment?				
Associated Hypotheses: H2. Attractant flow releases at Fort Peck will result in increased reproductive success through increased aggregation and spawning success of adults.				
BQ1/L1/C1-- Design study: complementary passive telemetry network	Detectability of telemetry tags by network receivers, variation of tag detectability with discharge-related characteristics, tag cost, tag reliability.	IF fish movements past strategic locations are successfully detected, THEN deploy a larger network of telemetry receivers to help evaluate sturgeon response to flow.	1	C1-C2 all concurrent. Also with design of lower basin telemetry network (Table 39 - BQ1/L1/C1)
BQ1/L1/C2 – Field study: opportunistic tracking of reproductive behaviors	Degree of association of reproductive behaviors and successful spawning with monitored hydrologic characteristics.	IF there are moderate to strong associations between hydrologic characteristics and reproductive behavior, THEN this provides stronger evidence for L2 studies. However, IF successful reproductive behavior is observed in the absence of the hypothesized hydrologic characteristics AND is	4	C1-C2 concurrent

Question, Level and Study Components	Key Metrics	Simplified IF - THEN Decision Criteria	Degree of Certainty *	Concurrent / Dependent Components
		sufficient to have a population-level effect THEN this provides evidence against hypothesis H2.		
Big Question 2 – Food and Forage: Can naturalization of the flow regime from Fort Peck contribute to increased food production, foraging habitat, and survival of age-0 sturgeon?				
Associated Hypotheses: H1. Naturalized flow releases at Fort Peck will result in increased productivity through increased hydrologic connections with low-lying land and flood plains in the spring, and decreased velocities and bioenergetic demands on exogenously feeding larvae and juveniles during low flows in summer and fall.				
No science components prioritized for first five years after ROD for BQ2 and H1. Postpone work on BQ2 until work on BQ5 is completed.				
Big Question 3 – Temperature Control: Can water-temperature manipulations at Fort Peck contribute significantly to increased chance of reproduction and recruitment?				
Associated Hypotheses: H4. Warmer flow releases at Fort Peck Dam will increase system productivity and food resource availability, thereby increasing growth and condition of exogenously feeding larvae and juveniles. H5. Warmer flow releases from Fort Peck Dam will increase growth rates, shorten drift distance, and decrease mortality by decreasing free embryos transported into headwaters of Lake Sakakawea.				
During first five years after ROD, focus on science components within BQ3 that are supportive of investigations under BQ5.				
BQ3/L1/C2b - lethality of Lake Sakakawea to age-0	2b – Spatial and temporal extent and variability of conditions lethal to benthic larval fish in Lake Sakakawea.	IF results indicate that Lake Sakakawea is not limiting, THEN this provides more support for Level 2 experiments.	3	C2b, C3b and C4b all concurrent
BQ3/L1/C3b – Field studies: validating advection / dispersion model	3b – Spatial and temporal distributions of larvae and surrogate flow tracers to determine larval retention.	IF results indicate that free embryos can be retained in the Fort Peck segment THEN this provides more support for Level 2 experiments.	3	C2b, C3b and C4b all concurrent
BQ3/L1/C4b – Mesocosm studies: developing quantitative temperature-recruitment relationships	4b – Temperature-dependence of pallid sturgeon developmental rates.	IF data on developmental rates and other evidence indicates that drift/dispersal is not limiting, THEN this provides more support for Level 2 experiments.	4	C2b, C3b and C4b all concurrent

Question, Level and Study Components	Key Metrics	Simplified IF - THEN Decision Criteria	Degree of Certainty *	Concurrent / Dependent Components
Big Question 4 – Sediment Augmentation: Can sediment bypass at Fort Peck contribute significantly to increased chance of reproduction and recruitment?				
Associated Hypotheses: H6. Installing sediment bypass at Fort Peck will increase and naturalize turbidity levels, resulting in decreased predation on embryos, free embryos, and exogenously feeding larvae.				
No science components prioritized for first five years after ROD for BQ4 and H6. Postpone work on BQ4 until work on BQ5 is completed.				
Big Question 5 – Drift Dynamics: Can combinations of flow manipulation from Fort Peck, drawdown of Lake Sakakawea, and fish passage at Intake Dam on the Yellowstone River increase probability of successful dispersal of free embryos and retention of exogenously feeding larvae?				
Associated Hypotheses: H3. Reduction of mainstem Missouri flows from Fort Peck Dam during free-embryo dispersal will decrease mainstem velocities and drift distance, thereby decreasing mortality by decreasing numbers of free embryos transported into headwaters of Lake Sakakawea. H7. Fish passage at Intake Diversion Dam on the Yellowstone River will allow access to additional functional spawning sites, increasing spawning success and effective drift distance, and decreasing downstream mortality of free embryos and exogenously feeding larvae.				
H10. Drawdown of Lake Sakakawea will increase effective drift distance, decreasing downstream mortality of free embryos and exogenously feeding larvae.				
BQ5/L1/C1a,b – Modeling / engineering study: drift dynamics and effects of anoxia	1a – Integrated model linking hydrodynamics, water temperature increases, developmental rates, and population dynamics. 1b – Spatial/temporal variation of anoxia in Lake Sakakawea. <u>Overall:</u> length of free-flowing river under drawdown and flow scenarios; frequency of occurrence	Complete C2 regardless of C1 outcomes. IF model results show that biologically significant movement of the anoxic zone is substantial across management scenarios, THEN this provides more support for L2 drawdown management actions.	1	C1, C2, C3 and C4 completed concurrently
BQ5/L1/C2a,b - Screening: anoxia-dependent recruitment limitation	2a - Spatial / temporal extent and variability of anoxia in Lake Sakakawea. 2b – Spatial distributions of suitable spawning habitat upstream of Intake Dam.	IF results indicate that anoxic zones are patchy, dispersal into Lake Sakakawea is not necessarily fatal AND suitable spawning habitat exists to take advantage of greater passage, THEN this provides more support for L2 drawdown management actions, and potentially other actions.	1	C1, C2, C3 and C4 completed concurrently
BQ5/L1/C3 – Field studies: validating temperature, drift, and	Spatial and temporal distributions of larvae and surrogate flow tracers to determine larval retention.	IF drift experiments show that advection is significantly different than predicted in passive transport models, THEN this provides more	2	C1, C2, C3 and C4 completed concurrently

Question, Level and Study Components	Key Metrics	Simplified IF - THEN Decision Criteria	Degree of Certainty *	Concurrent / Dependent Components
recruitment relationships		support for L2 drawdown management actions.		
BQ5/L1/C4 – Mesocosm experiments: Larval dispersal rates	Virtual velocity of free embryos as a function of time, temperature, and developmental stage in relation to channel complexity.	IF results provide robust relationships among abiotic variables, developmental stages, and dispersal rates AND results of C1-3 indicate anoxia is patchy and retardation mechanisms can be identified and quantified, THEN use this information to inform design of L2 studies.	4	C1, C2, C3 and C4 completed concurrently. All mesocosm studies designed concurrently.
Big Question 6 – Population Augmentation. Can population augmentation (stocking) processes be enhanced to increase survival and genetic fitness of stocked fish?				
Associated Hypotheses: H8. Stocking at optimal size classes and in optimal numbers will increase growth rates and survival of exogenously feeding larvae and juveniles. H9. Stocking with appropriate parentage and genetic diversity will result in increased survival of embryos, free embryos, exogenously feeding larvae, and juveniles.				
BQ6/L1/C1 - Engineering studies: feasibility hatchery needs, facilities, operations	Costs and measures of likely survival for a range of propagation facility designs.	IF alternative designs are expected to produce population benefits at a reasonable cost, THEN this provides more support for L2 management experiments	4	C1-C3 done concurrently
BQ6/L1/C2 - Retrospective study: survival linked to hatchery operations	Number and survival probabilities for stocked pallid sturgeon by stocked size, hatchery of origin, location of release and health history.	IF results indicate that changes in propagation facility operations could increase survival, THEN this provides more support for L2 management experiments. IF results indicate that more fish releases are required to estimate survival probabilities, then review alternative designs for BQ6/L2/C4.	3	C1-C3 done concurrently
BQ6/L1/C3 - Simulation models: population sensitivity to size, health, genetics	Probability of quasi-extinction, instantaneous growth rates, and sensitivity measures under various model scenarios.	IF results indicate that population dynamics are sensitive to changes in augmentation practices AND the information provided by previous components shows the need for L2 studies THEN this provides more support for L2 management experiments	4	C1-C3 done concurrently

Question, Level and Study Components	Key Metrics	Simplified IF - THEN Decision Criteria	Degree of Certainty *	Concurrent / Dependent Components
BQ6/L2/C4 – Manipulative field experiments: varying size, location of stocking	Estimated number and survival probabilities for stocked pallid sturgeon by stocked size and age, hatchery of origin; fish condition; water year conditions, and release location.	IF results indicate that survival is sensitive to size or age at stocking, THEN proceed to L3 implementation.	4	Decision criteria met for all three BQ6/L1 studies

1

Table 44. Overview of highest priority Level 1 and 2 science components for the Lower Missouri, anticipated to be completed within the first five years of the Record of Decision (ROD) (subject to budget and resource constraints). Appendix C contains a complete list of all Level 1 and 2 components, and Appendix F describes the prioritization process. Components listed in Appendix C but not in this table could be implemented beyond the 5-year post-ROD period. Metrics, and decision criteria with associated degrees of certainty for the working management hypotheses are summarized from Appendix C. Categories for Degree of Certainty: 1 = Definitive, 2 = Statistically rigorous, 3 = Indicative but not authoritative, 4 = Expert judgement of multiple lines of evidence required, BQ = Big Question, L = Level, C = Component. (e.g., BQ1/L1/C2 is Big Question 1, Level 1, Component 2). Work under BQ6 subject to Recovery Team discussions and Propagation Strategy. Hypotheses are from Table 1 in Jacobson et al. 2016a.

Question, Level and Study Components	Key Metrics	Simplified IF - THEN Decision Criteria	Degree of Certainty*	Concurrent / Dependent Components
Big Question 1 – Spawning Cues: Can spring pulsed flows synchronize reproductive fish, increase chances of reproduction and recruitment?				
Associated Hypotheses: H11. Naturalization of the flow regime at Gavins Point Dam will improve flow cues in spring for aggregation and spawning of reproductive adults, increasing reproductive success.				
BQ1/L1/C1-Design study: complementary passive telemetry network and biological modeling of potential population benefits	1a) Detectability of telemetry tags by network receivers, variation of tag detectability with discharge-related characteristics, tag cost, tag reliability. 1b) Power analysis to determine how many tagged adults required to detect various differences in level of spawning. Development of population model to model potential population benefits of spring pulsed flows as a function of frequency of implementation. 1c) Modeling analysis to determine required level of spawning to support a sustainable population	IF fish movements past strategic locations are successfully detected, THEN deploy a larger network of telemetry receivers to help evaluate sturgeon response to flow.	1	BQ1/L1 – C1, C2 done concurrently
BQ1/L1/C2 – Field study: Opportunistic tracking of reproductive behaviors	Degree of association of reproductive behaviors and successful spawning with monitored hydrologic characteristics.	IF there are moderate to strong associations between hydrologic characteristics and reproductive behavior, THEN this provides stronger evidence for L2 studies. However, IF successful reproductive behavior is observed in the absence of the hypothesized hydrologic characteristics AND is sufficient to have a population-level effect THEN	4	BQ1/L1 – C1, C2 done concurrently

Question, Level and Study Components	Key Metrics	Simplified IF - THEN Decision Criteria	Degree of Certainty*	Concurrent / Dependent Components
		this provides strong evidence to reject the hypothesis H11.		
Big Question 2 – Temperature Control: Can water-temperature manipulations at Fort Randall and/or Gavins Point contribute significantly to increased chance of reproduction and recruitment?				
Associated Hypotheses: H15. Operation of a temperature management system at Fort Randall Dam and/or Gavins Point Dam will increase water temperature downstream of Gavins Point, providing improved spawning cues for reproductive adults.				
BQ2/L1/C1 – Modeling study: water temperature management options, Gavins Point and Fort Randall	Absolute water temperatures and changes relative to historical values downstream of Gavins Point Dam and Fort Randall across various temperature control implementations, cost effectiveness.	IF temperatures are significantly lower than historical values, THEN this provides more support for other L1 studies.	2	Prerequisite for other L1 studies
Big Question 3 – Food and Forage: Can naturalization of the flow regime or channel reconfiguration (alone or in combination) contribute to increased food production, foraging habitat, and survival of age-0 sturgeon?				
Associated Hypotheses: H12. Naturalization of the flow regime at Gavins Point Dam will improve connectivity with channel-margin habitats and low-lying flood plain lands, increase primary and secondary production, and increase growth, condition, and survival of exogenously feeding larvae and juveniles. H13. Naturalization of the flow regime at Gavins Point Dam will decrease velocities and bioenergetic demands, resulting in increased growth, condition, and survival for exogenously feeding larvae and juveniles. H17. Re-engineering of channel morphology in selected reaches will increase channel complexity and bioenergetic conditions to increase prey density (invertebrates and native prey fish) for exogenously feeding larvae and juveniles. H18. Re-engineering of channel morphology will increase channel complexity and minimize bioenergetic requirements for resting and foraging of exogenously feeding larvae and juveniles.				
BQ3/L1/C1 - Screening: limitations of food or forage habitats	Indicators of starvation or impending death of age-0 sturgeon based on stomach contents (empty/full) or physiological indicators (lipid content).	IF results indicate bioenergetic constraints, THEN this provides more support for L2 experiments.	3	BQ3/L1 -C1, C2, and C3 done concurrently
BQ3/L1/C2 – Engineering study: Technology development for IRC sampling, modeling, measurement	Density, transport, and flux of food items (chironomid larvae) and estimates of age-0 survival rates in prospective IRCs obtained through measurement and modeling.	IF results demonstrate a spatial relationship between food and forage habitats AND food flux is a significant factor in growth and survival within and among IRCs, THEN this provides more support for L2 experiments.	2	BQ3/L1 -C1, C2, and C3 done concurrently
BQ3/L1/C3 - Field studies: food and forage habitat gradients	Depths, velocities, substrate, and spatial complexity of habitat, as well as whether habitats are occupied by food items	IF results demonstrate a systematic spatial relationship between habitat characteristics and selection by food sources and age-0	3	BQ3/L1 -C1, C2, and C3 done concurrently

Question, Level and Study Components	Key Metrics	Simplified IF - THEN Decision Criteria	Degree of Certainty*	Concurrent / Dependent Components
	(chironimids) and foragers (age-0 sturgeon).	fish, this provides more support for L2 experiments.		
BQ3/L1/C4 - Mesocosm studies: quantitative habitat-survival relations	Depths, velocities, substrate, and spatial complexity of habitat, as well as relative growth rates and survival as a function of habitat characteristics.	IF results demonstrate a systematic relationship between habitat characteristics and growth/survival, THEN this provides more support for L2 experiments.	1	Complete this component unless BQ3/L1/C2 provides alternative methods of estimating survival in the field
BQ3/L2/C5 - Design studies: effect of channel reconfigurations on IRCs	Relative performance of designs, measured as areas of functional habitat, using linked hydraulic and biological models.	IF demonstrated ability to increase habitat components benefiting growth and survival without unacceptable risks to other authorized purposes, THEN proceed to C6 field experimentation.	4	Develop concurrently with BQ3/L1 studies
BQ3/L2/C6 - Manipulative field experiments: effect of channel reconfigurations on IRCs	Area of food-producing habitat, area of foraging habitat, catch per unit effort of age-0 sturgeon, stomach contents, and lipid content.	IF results support the hypothesis that channel reconfigurations can provide increased functional habitats, THEN move to L3 implementation.	4	Described in section 4.2.6.3
Big Question 4 – Drift Dynamics: Can naturalization of the flow regime or channel reconfiguration (alone or in combination) contribute to decreased direct mortality and increased interception of free embryos into supporting habitats?				
Associated Hypotheses: H14. Alteration of the flow regime at Gavins Point Dam can be optimized to decrease main stem velocities, decrease effective drift distance, and minimize mortality of free embryos. H19. Re-engineering of channel morphology in selected reaches will increase channel complexity and serve specifically to intercept and retain drifting free embryos in areas with sufficient prey for first feeding and for growth through juvenile stages.				
BQ4/L1/C1 - Technology development: surrogate particles, particle tracking applied to IRCs	Recovery rate of marked particles in tracer studies and strength of model predictions for particle fate (combination of 1D and 2D models).	IF methods can provide strong inference on transport pathways, THEN this provides more support for L2 experiments.	1	C1-C6 done concurrently with L1 IRC studies under BQ3
BQ4/L1/C2 – Field studies: Resilience, stamina in turbulent flows	Survival of free embryos related to measures of fluid stress, including turbulent intensity and shear.	IF survival is sensitive to range of river velocities, turbulence, or shear during dispersal, THEN this provides more support for L2 experiments.	3	C1-C6 done concurrently with L1 IRC studies under BQ3
BQ4/L1/C3 - Field studies: free embryo exit paths	Proportion of surrogate particles (real or computational) that exit the thalweg and are retained in IRCs under	IF advection of surrogate or digital particles varies substantially with discharge or channel configuration,	4	C1-C6 done concurrently with L1 IRC

Question, Level and Study Components	Key Metrics	Simplified IF - THEN Decision Criteria	Degree of Certainty*	Concurrent / Dependent Components
	various channel geometries.	THEN this provides more support for L2 experiments.		studies under BQ3
BQ4/L1/C4 – Field studies: age-0 survival and complexity across flow gradients	Catch per unit effort of free embryos and measures of channel complexity relevant to interception hydraulics.	IF there are moderate to strong associations between advection metrics and channel configuration options, THEN this provides more support for L2 experiments.	4	C1-C6 done concurrently with L1 IRC studies under BQ3
BQ4/L1/C5 – Field studies: Free embryo transport to Mississippi River	Estimated number and survival of age-0 to juveniles hatched in the Missouri that reach the Mississippi River, relative to the number and survival of those that remain in the Missouri River.	IF the population of Missouri free embryos recruiting in the Mississippi River is NOT high enough to sustain the Missouri population, THEN increase effort to intercept free embryos in the Missouri River.	3	C1-C6 done concurrently with L1 IRC studies under BQ3; C5 dependent upon feasibility assessment
BQ4/L1/C6 – Modeling studies and field experiments: embryo dispersal tracking	Distributions of free embryos or other tracers, over time and space, as the constituents disperse downstream over a range of opportunistic flows.	IF field tracking data validate the outputs of drift models over a range of opportunistic flows, THEN proceed to proceed with L2 field experiments.	4	C1-C6 done concurrently with L1 IRC studies under BQ3
BQ4/L2/C7 - Engineering study: designs for interception experiments	Range of engineering designs that meet practical hydraulic needs and contribute to interception of drifting free embryos, and their cost.	IF designs provide evidence that IRCS contribute to growth and survival of age-0 pallid sturgeon, without unacceptable risk to other authorized purposes, THEN proceed to C8 manipulative field experiments.	4	Follows BQ4/L1 work

Big Question 5: Spawning Habitat. Can channel reconfiguration and spawning substrate construction increase probability of survival of eggs through fertilization, incubation, and hatch?

Associated Hypotheses:

H16. Re-engineering of channel morphology in selected reaches will create optimal spawning conditions -- substrate, hydraulics, and geometry -- to increase probability of successful spawning, fertilization, embryo incubation, and free-embryo retention.

BQ5/L1/C1 –Field study: functional spawning habitat, Yellowstone River	River depth, velocity, substrate, and habitat stability of documented spawning habitat, and reproductive responses of adults and embryos.	IF there is sustained moderate to strong spawning habitat selection that contrasts strongly with Lower Missouri River results, AND the results agree with spawning habitats quantified for other sturgeon species, THEN this provides more support for spawning habitat designs that mimic Yellowstone spawning.	3	C1-C3 concurrent
--	---	--	---	------------------

Question, Level and Study Components	Key Metrics	Simplified IF - THEN Decision Criteria	Degree of Certainty*	Concurrent / Dependent Components
BQ5/L1/C2 – Retrospective study: habitat condition gradients LMOR	River depth, velocity, substrate, habitat stability of documented spawning habitat, and reproductive responses of adults and embryos.	IF there is sustained moderate to strong spawning habitat selection that contrasts strongly with Yellowstone River results, THEN this provides more support for spawning habitat designs that mimic Lower Missouri spawning.	3	C1-C3 concurrent
BQ5/L1/C3 - Mesocosm studies: spawn conditions, behaviors	Hatch rate as a function of different combinations of depth, velocity, substrate, and hydraulic variables, with water quality and fish behaviors as covariates.	IF results provide quantitative criteria for abiotic (and biotic) variables influencing spawning behavior from aggregation of adults to hatch of embryos, THEN proceed to L2 field experiments.	3	C1-C3 concurrent C3 concurrent w other mesocosm studies
BQ5/L2/C4 - Engineering studies: sustainable design	Design performances, measured as ability to create the hydraulic and substrate conditions developed in components 1-3. Evaluate appropriate segments for spawning habitat using combined advection dispersion and population model	IF designs are judged capable of achieving functional spawning habitat while minimizing adverse effects to other authorized purposes, THEN proceed to C5 manipulative field experiments.	1	Build on learning from L1 C1-C3 studies
BQ5/L2/C5 - Manipulative field experiments: spawning habitat	Use of spawning sites compared to other areas; Hatch rate, as determined by catch per unit effort of free embryos or alternative techniques. See section 4.2.6.3.	IF created spawning patches are functioning as intended to improve spawning success, THEN proceed to L3 implementation	4	Build on learning from L1 C1-C4 studies
Big Question 6: Population Augmentation. Can population augmentation (stocking) processes be enhanced to increase survival and genetic fitness of stocked fish?				
Associated Hypotheses: H20. Stocking at optimal size classes and in optimal numbers will increase growth rates and survival of exogenously feeding larvae and juveniles. H21. Stocking with appropriate parentage and genetic diversity will result in increased survival of embryos, free embryos, exogenously feeding larvae, and juveniles.				
BQ6/L1/C1 – Engineering studies: feasibility hatchery needs, facilities,operations	Costs and measures of likely survival for a range of propagation facility designs.	IF designs are expected to produce population benefits at a reasonable cost, THEN this provides stronger support for L2 studies	4	C1-C3 done concurrently
BQ6/L1/C2 - Retrospective study: survival linked to hatchery operations	Number and survival rates for stocked pallid sturgeon by stocked size, hatchery of origin, and health history.	IF results indicate that changes in propagation facility operations could increase survival, THEN this	3	C1-C3 done concurrently

Question, Level and Study Components	Key Metrics	Simplified IF - THEN Decision Criteria	Degree of Certainty*	Concurrent / Dependent Components
		provides stronger support for L2 studies		
BQ6/L1/C3 – Modeling study: population sensitivity to size, health, genetics	Probability of quasi extinction, instantaneous growth rates, and sensitivity measures under various model scenarios.	IF results indicate that population dynamics are sensitive to changes in augmentation practices AND the information provided by previous components are not sufficient to make specific implementation decisions, THEN this provides stronger support for L2 studies	4	C1-C3 done concurrently
BQ6/L2/C4 - Field study: varying size, location of stocking	Differential survival as a function of size/age at stocking and other variables. See section 4.2.6.1	IF results indicate that survival is sensitive to size at stocking, and that changes are warranted in current practices THEN proceed to adjust L3 implementation.	4	Build on results from L1 studies

1

2 The following two sections (4.2.5 and 4.2.6) describe some of the details of those Level 3
 3 Actions which are either currently being implemented (e.g., propagation), or have been
 4 proposed for implementation in the near to medium term through policy
 5 determinations (e.g., spawning habitat, interception and rearing habitat, spawning cue
 6 flows). Appendix K provides a summary of metrics used to detect the effectiveness of
 7 various actions, as well as metrics used for tracking the status and trends of the pallid
 8 sturgeon population.

9 **4.2.5 Details on Level 3 Actions (and associated Level 2 Components) for Upper
 10 Missouri River**

11 This section provides more details on each of the Level 3 actions included in the
 12 MRRMP-EIS, describing the scope of the action, as well as the associated hypotheses,
 13 objectives, metrics, experimental designs, decision criteria, and contingent actions (if
 14 the outcomes are different from those anticipated). The EA recognizes the impacts of
 15 fragmentation in the Upper Missouri River imposed by dams which pose barriers to
 16 upstream migration of adults and of limited drift/dispersal distances of embryos. As
 17 well, recent analyses of anoxic conditions in Fort Peck Lake have been used to argue that
 18 such conditions in Lake Sakakawea would also be lethal to drifting free embryos,
 19 thereby potentially limiting natural recruitment. Currently, the wild pallid sturgeon
 20 population in the Upper River is dominated by old-age individuals.

21 Upper River Big Questions relate to management actions that are hypothesized to
 22 increase natural recruitment (see Table 40 and Table 43). The Level 3 actions described

1 here are based on the scientific considerations and policy determinations that have been
2 made to focus implementation on actions that are either proposed (fish passage at
3 Intake Diversion Dam) or are currently being implemented (population augmentation).
4 A detailed summary of all Level 1 and 2 actions is contained in Appendix C. It is possible
5 that over time, other potential actions may move from L1 feasibility analyses to L2 or L3
6 implementation (Figure 65).

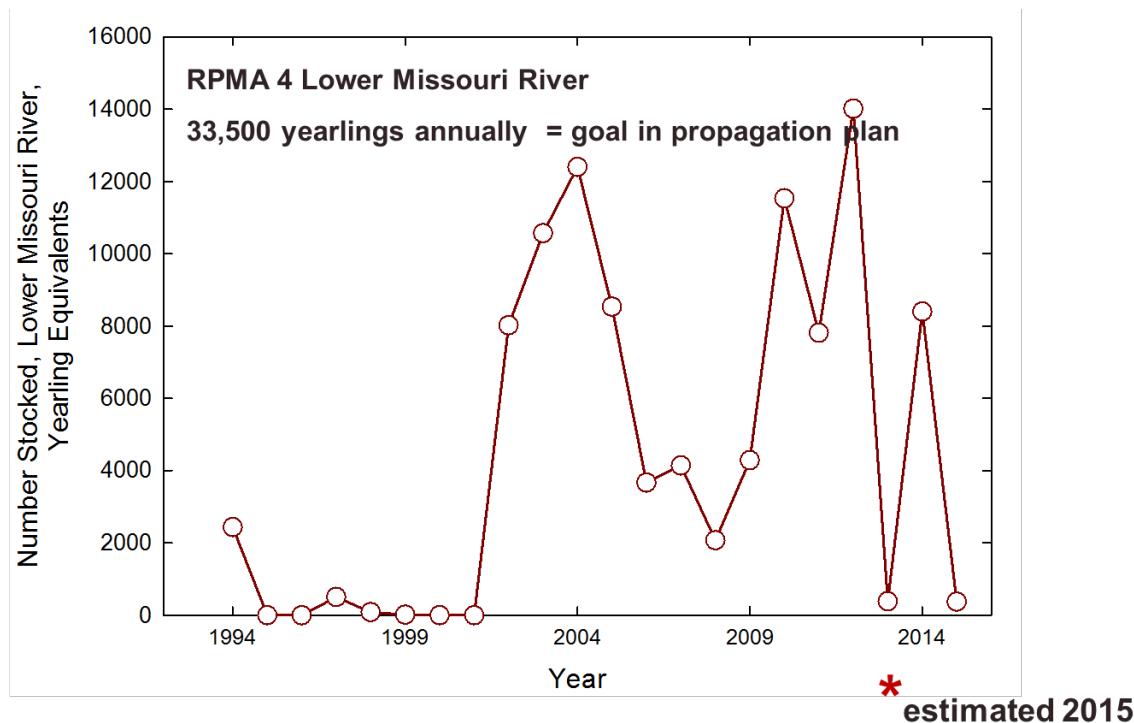

7 4.2.5.1 *Population augmentation*

8 4.2.5.1.1 *Introduction*

9 This introduction provides an overview of issues associated with population
10 augmentation for both the Upper and Lower Missouri River. Since 1998, population
11 augmentation (stocking) of pallid sturgeon has occurred at a level intended to have a
12 measurable effect on the population. Three federal hatcheries (Gavins Point National
13 Fish Hatchery, Garrison Dam National Fish Hatchery, and Neosho National Fish
14 Hatchery) and three state hatcheries (Blind Pony State Fish Hatchery, Miles City State
15 Fish Hatchery, and Bozeman Fish Technology Center) are involved with propagation of
16 Missouri River pallid sturgeon. Pallid sturgeon have been stocked into four Resource
17 Priority Management Areas (RPMA), now reorganized into four Management Units
18 (Appendix D; Figure D.1).

19 Population augmentation is designed to ensure genetic diversity using local and wild
20 broodstock collection (Pallid Sturgeon Recovery Team 2008). In 2014, hatcheries
21 stocked a combined 24,309 fingerling and yearling-sized pallid sturgeon from the 2013
22 and 2014 year classes into the RPMA (draft MRRMP-EIS). In the last 10 years (M.
23 Colvin, unpub. hatchery operations data), releases from hatcheries have either been
24 fingerlings (spawned in spring and released in fall; released 50 to 110 (mean 90) days
25 post-spawn in RPMA 2, now part of the Great Plains Management Unit) or yearlings
26 (spawned in spring and released in spring of the next year; 260 to 500 (mean 360) days
27 post-spawn in RPMA 2)¹. Fingerlings released in RPMA 4 are 50-70 days older on
28 average for both categories. There have been occasional releases of age 2 or older fish,
29 but these are quite rare now. Historically, year to year variation in releases of yearling
30 equivalents has been relatively high with ongoing challenges in meeting propagation
31 targets in the Lower Missouri River, specifically in RPMA 4 (Figure 66). A contributing
32 factor related to these challenges has been a lack of availability of genetically strong
33 adult pallid sturgeon. There is also year-to-year variation in the locations of stocking
34 across the Missouri River (Figure 66 and Figure 67).

¹ In terms of the generalized conceptual model in Figure 60, fingerlings and yearlings < 1 year old fit into the life stage of “exogenously feeding larvae”, while yearlings > 1 year old correspond to the start of the “Juvenile” life stage.

1

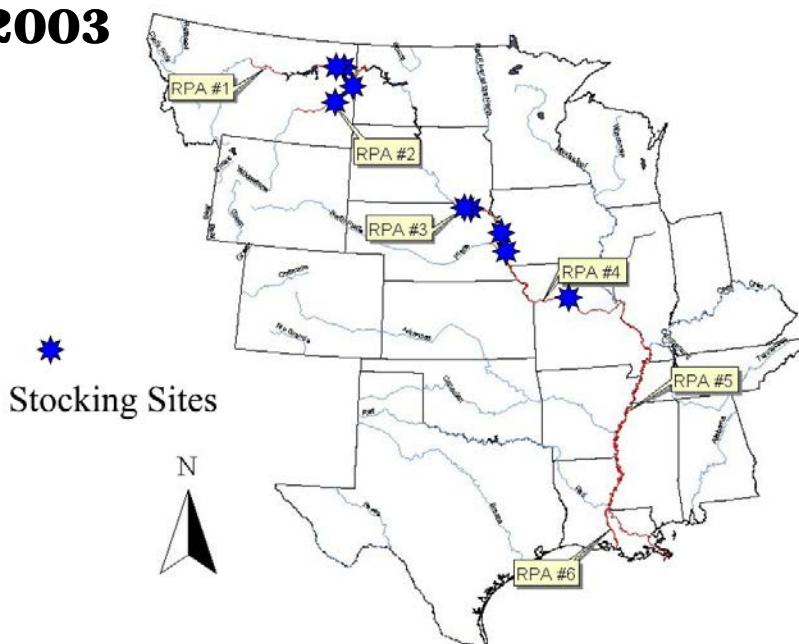

2 Figure 66. Stocking history for pallid sturgeon in the Lower Missouri River (summary of yearling equivalent
3 stocking data for RPMA4). The 2015 value is a preliminary estimate.

4 A variety of marking methods have been used to identify hatchery fish in subsequent
5 recoveries (Krentz et al. 2005). The Passive Integrated Transponder (PIT) tag is
6 typically implanted in fish larger than 160 mm since tag losses are known to increase as
7 the size of fish and experience of tagging crew decreases. Smaller juveniles (that cannot
8 be PIT tagged based on size) are marked with an elastomer tag (visual) or coded wire tag
9 (CWT) or by scute¹ removal which has been incorporated within the past several years.
10 Genetic records are now kept for all releases so genetic identification of recaptured fish
11 can identify the year class of release. If a fish is recaptured without a PIT tag, one is
12 inserted (if the fish is large enough) for future identification.

13 Reviews of stocking data have been used to inform stocking plans (e.g., USFWS 2007).
14 Importantly, a Pallid Sturgeon Basin-wide Stocking and Augmentation Plan will be
15 developed over the coming year by the Pallid Sturgeon Recovery Team and participating
16 federal agencies due to concerns related to fish health/disease, genetics, stocking size,
17 numbers/carrying capacity, stocking practices, etc. This plan is expected to evaluate
18 monitoring, hatchery use, genetics, propagation, database management and research in
19 the context of recovery concerns for Pallid Sturgeon.

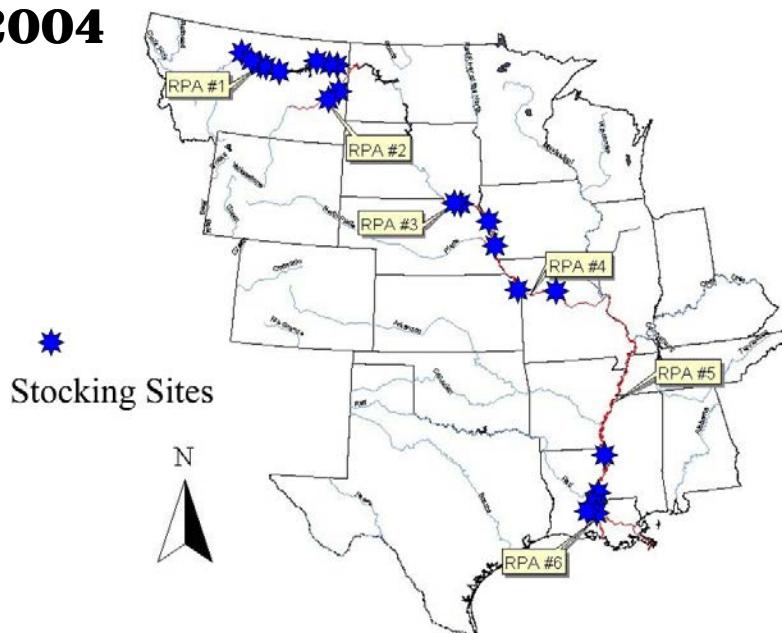

¹ Scutes are armor-like structures on the sides and back of pallid sturgeon

2003

2

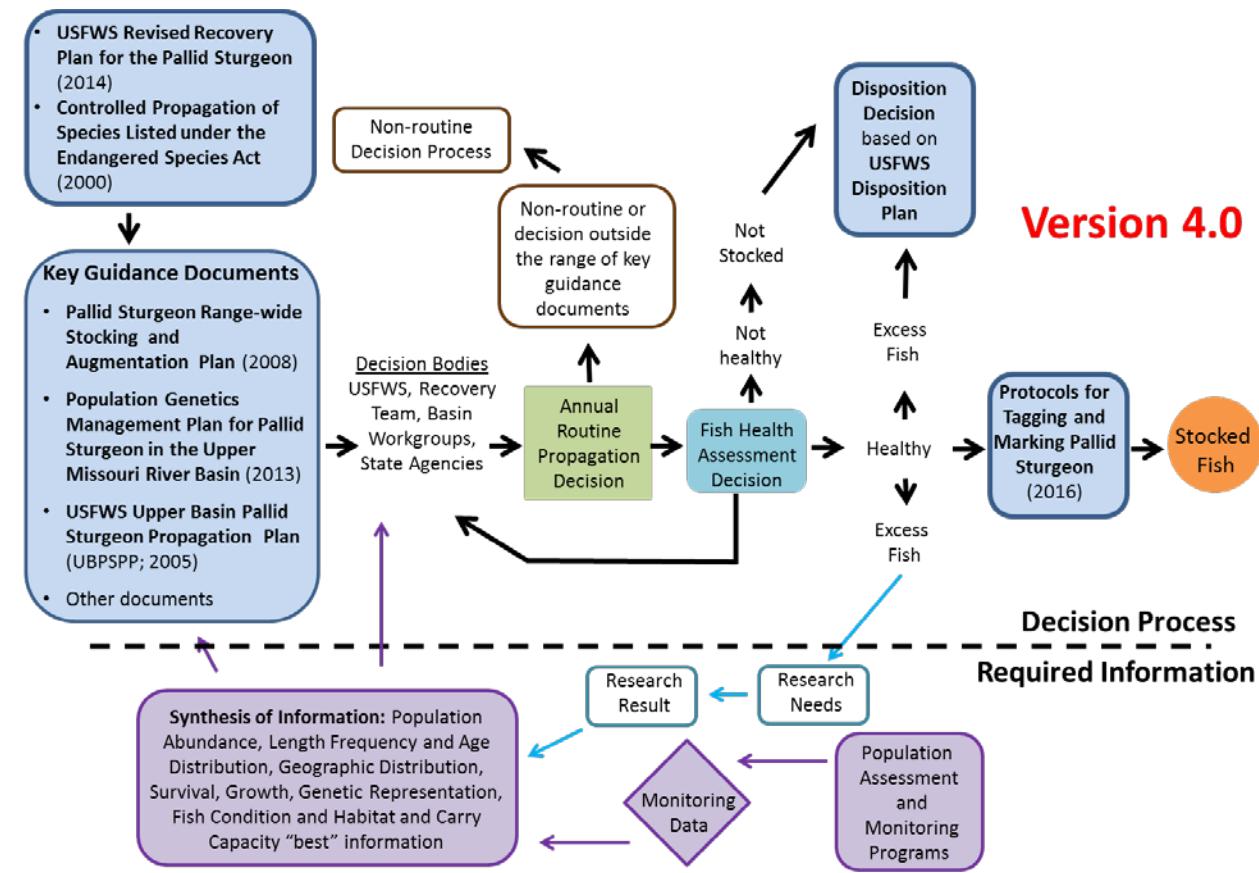

3 Figure 67. Location of stocking sites for pallid sturgeon across its range in 2003 and 2004 (Krentz et al.
4 2005). RPA = Recovery Priority Area.

5 Changes to current stocking practices that are recommended in the stocking and
6 augmentation plan will need to be integrated into this AM Plan. This AM Plan defers to
7 existing or future governance structures for decision making which recognize that the
8 Upper Basin and Middle Basin Working Groups and Pallid Sturgeon Recovery Team
9 alongside participating agencies have established roles in the conservation and recovery
10 of Pallid Sturgeon that may influence actions that relate to AM. For instance, while the

1 authority and responsibility for hatchery management lie with the USFWS for those
2 facilities operated by the USFWS, other entities (e.g., Montana Fish Wildlife and Parks)
3 are responsible for hatchery operations. However, the USFWS has the responsibility for
4 oversight of all pallid sturgeon propagation efforts, including providing direction on
5 rearing and stocking strategies, genetics, stocking targets, etc. through the forthcoming
6 Basin-wide Stocking and Augmentation Plan. Much of the existing information collected
7 in the Missouri and Yellowstone rivers has been due in part to collaborative efforts
8 among agencies.

9 This AM Plan further recognizes that a number of key documents have been developed
10 to provide guidance for the population augmentation program and a framework for
11 routine and non-routine decision making. Among others, these documents include the
12 Pallid Sturgeon recovery plan (USFWS 2014), Rangewide Stocking and Augmentation
13 plan (Jordan 2008), as well as the Genetics Management (Heist et al. 2013) and
14 Propagation Plans for the Upper Basin (USFWS 2005). Moreover, the Pallid Sturgeon
15 Population Assessment Program (PSPAP) provides important inputs to decision making
16 by collecting data on survival, movement, distribution, and habitat use, ultimately for
17 the purpose of assessing population abundance, length frequencies, age distribution,
18 geographic distribution, survival, growth, genetic representation, fish fitness (i.e.,
19 condition), habitat use, and carrying capacity. Figure 68 illustrates the annual decision
20 process and information inputs for population augmentation in the Upper Basin.

21 The following sections focus on the fate of fish after leaving the hatchery (in terms of
22 ultimate changes to the population), and are meant to illustrate examples of how
23 alternative actions can be systematically and rigorously evaluated. In the context of AM,
24 many level 1 and 2 science activities and some level 3 and 4 activities related to
25 propagation are or will be funded by the USACE to help avoid jeopardy of Pallid
26 Sturgeon. These actions are intended to be complimentary examples to work of the
27 USFWS around hatchery practices and broader activities of the Recovery Team and
28 Working Groups. Although the details of related governance and decision making have
29 not been confirmed (see Chapter 2), the expectation is that decision authorities related
30 to propagation actions would still be retained within the USFWS and Recovery Team.

1

2 Figure 68. Annual decision making process, supporting documents, and information requirements for
 3 population augmentation in the Upper Basin. Source: USFWS “Adaptive Decision Making Process Associated
 4 with the Pallid Sturgeon Population Augmentation”

5 4.2.5.1.2 *Hypotheses*

6 The following management hypotheses from the EA are relevant to population
 7 augmentation in the Upper Missouri River:

- 8 • H8. Stocking at optimal size classes and in optimal numbers will increase growth
 9 rates and survival of exogenously feeding larvae and juveniles.
- 10 • H9. Stocking with appropriate parentage will increase genetic diversity and health of
 11 the population (as opposed to individuals) resulting in increased survival of
 12 embryos, free embryos, exogenously feeding larvae, and juveniles.

13 These hypotheses are intended to assist in clarifying evaluations of population level
 14 effects for a range of propagation actions including alternative sizes and numbers of
 15 releases (which relates to carrying capacity), locations, and genetic diversity/parentage.
 16 There are a wide range of perspectives and a strong basis of scientific evidence around
 17 population augmentation. These perspectives and the evidence need to be debated and
 18 discussed further through the Recovery Team and the USFWS which we expect would

1 be clarified in the forthcoming Basin-wide Stocking and Augmentation Plan. The AM
2 Plan recognizes that those discussions may lead to a different set of propagation
3 strategies, which will need to be carefully designed, implemented, monitored and
4 evaluated. Recent findings on deteriorating fish condition in the Lower Missouri River
5 indicate that fish condition of adult Pallid Sturgeon has been declining, starting in 2013
6 with increasing declines in 2014 and 2015 (Steffensen and Mestl 2016, Randall et al
7 2016). A variety of hypotheses have been proposed to explain this pattern, which include
8 a recognition of possible limits on the carrying capacity for pallid sturgeon, and
9 intraspecific competition. If evidence supports this hypothesis, there are potential
10 implications for the number of fish that can be stocked. Hence, the systematic and
11 rigorous evaluation of propagation strategies is crucial and needs to remain a consistent
12 attribute of all strategies, even if the strategies themselves are different from what
13 appears in the current AM Plan (e.g., hatchery releases are increased, decreased, or
14 modified from the status quo). Below we describe an example experimental design that
15 relates to testing the effect of release locations in the Upper River due to the potential
16 influence of proposed passage improvements at Intake Diversion Dam and the anoxic
17 environment in the headwaters of Lake Sakakawea which has the potential to affect
18 survival of hatchery fish. These hypotheses are linked to evaluations of other hypotheses
19 and their related actions (i.e., Big Question 5, H7 and H10). The metrics and analytical
20 methods used to test these hypotheses are outlined below. Hypotheses and possible
21 designs around actions involving numbers of release, size at release, and genetic
22 diversity are described in Section 4.2.6 (Lower River Level 3 actions), which could
23 similarly be applied in the Upper River.

24 Although other information gaps and specific hypotheses have been identified as
25 potentially important to address in the Upper River (e.g., skinny fish due to reduced
26 carrying capacity relative to number of fish stocked and changes in prey base /
27 predators), they have not been identified as priority hypotheses affecting propagation
28 actions at this time. Additional EA hypotheses may emerge from the new information
29 process (see Section 6.2.5). If additional EA hypotheses emerge, it will be important to
30 have L1 activities to develop rigorous experimental designs and L2 activities for testing
31 those designs.

32 *4.2.5.1.3 Action Description*

33 Propagation actions have been ongoing for some time at a level intended to benefit the
34 population (i.e., Level 3). As noted, a Basin-wide Stocking and Augmentation Plan is
35 forthcoming, so the implementation of propagation measures required under the MRRP
36 and partially funded by USACE will require close coordination with the Pallid Sturgeon
37 Recovery Team and Upper Basin Workgroup to ensure this AM plan supports and is
38 consistent with the Stocking and Augmentation Plan. Some additional and concurrent
39 Level 1 and Level 2 components may be considered to better understand how well

1 current methods of propagation have affect population outcomes and to explore
2 alternative approaches which might improve Level 3 actions (see Appendix C).

3 Propagation actions are generally similar for the Upper River as for the Lower River.
4 Sections 4.2.6.1 and 4.2.6.2 describe management experiments involving stocking fish at
5 variable numbers, sizes, and/or manipulating other hatchery factors to examine the
6 influence on early life survival. The proposed focus of a Level 2 study would be on
7 improved monitoring to understand the influence of location of stocking on early
8 survival, while holding as many other factors as constant as possible (e.g., genetic
9 diversity, size at release, hatchery origin) and accounting for other factors that naturally
10 vary year to year (e.g., water conditions). The AM Plan acknowledges that survival
11 estimates for different size classes are currently available and the purpose of this and
12 any additional monitoring would be to provide comparable data across the Upper and
13 Lower Rivers that can inform population modeling in support of AM (see Appendix D).
14 Any experimental design or adjustments in the location of stocking would need to be
15 coordinated with the Working Groups responsible for managing pallid sturgeon releases
16 and aligned with the stocking goals in the stocking and augmentation plan for the
17 management area.

18 *4.2.5.1.4 Objectives and Expected Benefits*

19 While population augmentation is *necessary* for recovery of the pallid sturgeon, it is not
20 *sufficient* because the ESA requires a self-sustaining population. While both the Upper
21 and Lower River have had difficulties in meeting propagation targets, the objective of
22 this Level 2 management experiment would be to identify release locations that improve
23 survival of free swimming larvae in the Upper River with the ultimate purpose of
24 supporting natural recruitment. More specifically, these actions are expected to provide
25 evidence about the influence of upstream distance and habitat differences (e.g., due to
26 passage structure at Intake and anoxic environment in Lake Sakakawea) on survival of
27 hatchery releases. Estimates of survival probabilities would be entered into the
28 population model to determine the ultimate impacts of actions on the Upper Missouri
29 River populations, and also to help in refining objectives / experimental design.

30 *4.2.5.1.5 Metrics*

31 Assessing the effect of stocking location requires understanding the fate of marked
32 hatchery releases in the Upper River, and ultimately the number that survive to age 2.
33 Hence, this action and most other propagation actions are closely tied to the population
34 monitoring program described in Appendix D. Specific metrics associated with releases
35 include hatchery of origin, number, size, timing, stocking location (or River Mile), site
36 and parental cross, and water conditions (e.g., water temperature, velocity, discharge,
37 turbidity, substrate). Upon recapture, key metrics include habitat/location of sample (or

1 River Mile), sampling method and intensity, number collected, size and age, hatchery of
2 origin, fish condition (length/weight), and water year conditions (to help explain
3 survival probabilities). These data can be used to generate key metrics for analyses, such
4 as proportion of recaptures from different release groups, catch efficiency, and
5 ultimately survival probabilities between early years of life (these methods are described
6 in more detail in section 4.2.6.1.3).

7 *4.2.5.1.6 Experimental Design*

8 This example of a management study is primarily intended to examine the effect of
9 release locations on early survival of hatchery fish between Rivers (e.g., Yellowstone and
10 Upper Missouri Rivers) and across River Miles (e.g., upstream and downstream release
11 locations on each River). We are aware that other examinations of stocking site and
12 river (Yellowstone vs. Missouri) has and continues to be evaluated in the Upper Basin
13 via survival analyses (by Jay Rotella at MSU), but these studies were not available at the
14 time of writing. Other important factors that need to be controlled or accounted for
15 include genetic diversity, hatchery of origin, number and size of releases, disease (e.g.,
16 ranavirus, iridovirus, fin curl, *Polypodium hydriforme*), and water conditions across
17 years.

18 Monitoring the fate of hatchery releases would require establishing spatial contrasts
19 across the Upper Missouri River basin. This monitoring would need to be part of the
20 broader population monitoring program including efforts targeted at free embryos that
21 would hypothetically be produced through natural spawning in the Yellowstone River
22 and have the potential to drift into the anoxic zone of Lake Sakakawea (see Appendix D).
23 On the Yellowstone River spatial contrasts would include using consistent release
24 locations upstream and downstream of the Intake Diversion Dam with a sufficient
25 distance between locations to ensure that habitat influences are independent of these
26 release locations. Likewise, Upper Missouri River spatial contrasts would include release
27 locations at upstream and downstream locations which should likely be close to past
28 stocking sites.

29 Temporally, it would be important to monitor sites close to the release location shortly
30 after release to examine whether local conditions affect metrics of fish response relative
31 to other sites with different local conditions. It is expected that monitoring would need
32 to occur across the spatial network for a number of years, which would depend on the
33 number of marked fish that are released. Available stocking information and low
34 capture efficiencies suggest that the number of marked releases may currently be too
35 low to detect an effect in a reasonable time frame. Power analyses would assist in better
36 identifying the number of releases that are required. Given the proposed fish passage at
37 Intake, it would also be important to establish a temporal baseline at upstream and

1 downstream locations before passage construction occurs to help evaluate whether the
2 structure has any additional effect on early survival.

3 If smaller fingerlings are used, fish would require elastomer markings to identify
4 hatchery of origin. An additional mark would be required to distinguish among release
5 locations for individuals with the same parentage that are released at different sites.
6 Upon recapture, destructive sampling of a sub-sample of individuals may be required to
7 assess genetics (unless technological improvements allow non-destructive genetic
8 sampling) and PIT-tags would be added once they have reached a sufficient size. If
9 larger fingerlings or yearlings are used, fish would be marked with PIT-tags. As noted in
10 Section 4.2.6, variants of a Cormack-Jolly-Seber (CJS) or more complex models would
11 be used to estimate survival of the release groups using multiple recapture occasions.
12 Standard analysis-of variance (ANOVA) methods could also be used to evaluate
13 differences in fish metrics across release groups (e.g., comparison of relative
14 proportions of release group sampled or comparison of fish condition across spatial
15 contrasts noted above). There would be challenges in interpreting some of these data
16 across sampling locations, however, since capture efficiencies can only be estimated
17 upon 2 successive captures. For instance, without repeated captures it will not be
18 possible to estimate if fish are absent from a sample because they died elsewhere in
19 relation to their release location or are simply absent because they are using a different
20 habitat.

21 *4.2.5.1.7 Decision Criteria*

22 Decision criteria guide the Technical and Implementation Teams when evaluating
23 monitoring and other information and in developing recommendations for
24 consideration by the agencies. Comparisons of relative or absolute measures across
25 spatial contrasts/locations would help determine the biological benefits of release
26 locations (i.e., different rivers and different upstream distances). As noted above,
27 estimates of survival probabilities of release groups across years would provide more
28 robust evidence about potential benefits. However, as fish mature and move throughout
29 the Upper River basin it would become increasingly difficult to isolate the effect of
30 release location from other factors. In contrast, data that are closer in time and space to
31 the actual release locations would be less reliable (i.e., provide only a relative measure of
32 observation), yet would be more strongly related to the effects of release location. As
33 such, there will be a need to evaluate multiple response measures over time and across
34 spatial locations in combination with modeling results and expert judgments to assess
35 whether different hatchery release locations have effects on early life survival. Once
36 better information has been gathered, Level 3 actions can be adjusted in combination
37 with improved knowledge about optimal numbers/carrying capacity, size, hatchery
38 operations, and genetic diversity of the releases from the propagation program.

1 4.2.5.1.8 *Level 3 Contingent Actions*

2 See Section 4.2.6 for a summary of uncertainties and contingencies related to
3 propagation.

4 4.2.5.2 *Passage at Intake Dam on Yellowstone River*

5 4.2.5.2.1 *Introduction*

6 The Bureau of Reclamation (Reclamation) operates Intake Diversion Dam on the
7 Yellowstone River 70 miles (112 km) upstream of the confluence with the Missouri
8 River. Construction of this structure was completed in 1909 as a 12-foot high wood and
9 stone dam to divert water from the mainstem into an irrigation canal that runs parallel
10 to the River and provides a dependable water supply for adjacent lands. Since its
11 construction, the Dam has impeded upstream migration of native fish and poses a
12 partial or complete barrier to different species (Reclamation and USACOE 2015).

13 In recent years, the U.S. Department of the Interior, Bureau of Reclamation and the U.S.
14 Army Corps of Engineers have been jointly evaluating proposed modifications to Intake
15 Diversion Dam that would reduce entrainment (related actions have already been
16 completed) and improve fish passage. Evidence suggests that the dam poses a barrier to
17 upstream migration of pallid sturgeon (Reclamation and USACOE 2015). As such,
18 improvements to fish passage are expected to assist in the recovery of pallid sturgeon in
19 the Upper Missouri River basin by providing access to up to 165 miles (264 km) of
20 habitat in upstream reaches of the Yellowstone River. Historically, Pallid sturgeon have
21 been documented about 112 miles (180 km) upstream of Intake at times of year when
22 spawning was known to occur (Brown 1955; 1971 as cited by Walsch 2015). The
23 hydrology, thermal conditions, and sediment regime in the Yellowstone River are seen
24 as providing habitat conditions that are suspected to be supportive for pallid sturgeon.
25 As well, additional drift distance may better allow for larval drift and recruitment,
26 although mean velocities on the Yellowstone are as much as 2 times higher than those
27 on the Upper Missouri for equivalent June flow exceedance.

28 The USACE is a joint lead agency for improvements to Intake since this action was
29 identified as a Reasonable and Prudent Alternative (RPA) in the USFWS 2003 Amended
30 Biological Opinion. As such, the USACE is working with Reclamation and others to
31 ensure that modifications are effective and the population response of pallid sturgeon is
32 well documented. In 2016, Reclamation released the final EIS and ROD, which
33 summarize the impacts of the proposed action (and alternatives to it) on environmental
34 and human resources (USBOR and USACE 2016a, 2016b). Appendix E of the EIS
35 (USBOR 2015) is a “Monitoring and Adaptive Management Plan”, focusing on
36 monitoring the effectiveness of fish passage to reduce uncertainties related to biological

1 performance, and ultimately improve passage operation over time. The Intake EIS
2 (USBOR and USACE 2016a) is a separate document from the MRRMP-EIS.

3 Given this context, any actions that are implemented by the USACE would need to be
4 closely coordinated with the Bureau of Reclamation and others (e.g., Pallid Sturgeon
5 Recovery Team and Upper Basin Workgroup). Additional studies and/or actions beyond
6 what are described here may be required or come to light resulting in changes to the
7 experimental design and related needs for information (e.g., possibly applying the
8 refined advection/dispersion model). Moreover, due to the lawsuit on the
9 implementation of passage around Intake Dam, there is considerable uncertainty
10 regarding the type of action that may be implemented and its related timing. As a result,
11 the different Level 2 study components described below depend somewhat on which
12 course of action is eventually pursued.

13 *4.2.5.2.2 Hypotheses*

14 The following management hypothesis is directly relevant to improvements in fish
15 passage at Intake Diversion Dam:

- 16 • H7. Fish passage at Intake Diversion Dam on the Yellowstone River will allow access
17 to additional functional spawning sites, increasing spawning success and effective
18 drift distance, and decreasing downstream mortality of free embryos and
19 exogenously-feeding larvae.

20 Stemming from this hypothesis are five broad monitoring questions that will clarify the
21 success of passage at Intake and its ability to help achieve the recovery goals in the
22 Upper Basin (see Section 4.1.1):

- 23 • Do motivated spawners and downstream adult migrants successfully move past
24 Intake?
25 • How far upstream do motivated spawners migrate?
26 • Does successful aggregation and spawning occur?
27 • Do free embryos successfully move downstream past Intake?
28 • Is recruitment successful and sufficient to meet population targets?

29
30 The unique in-river movements, life history stages, and agency responsibilities for
31 monitoring suggest the need for five study components to provide answers to these and
32 more specific underlying questions (discussed below in Section 4.2.5.2.3). Answers to
33 these questions would be further linked to a series of related decisions that might be
34 required to improve passage and ultimately assist in achieving recovery goals (discussed
35 in Section 4.2.5.2.7).

1 As noted by the summary of priority Level 1 and 2 study components under Big
2 Question 5 (Table 43), this hypothesis is also linked to other actions related to Missouri
3 River flows, drift distance, drawdown of Lake Sakakawea and mortality of free embryos
4 and exogenously feeding larvae. These linked hypotheses would be explored through the
5 Level 1 and Level 2 actions summarized in Table 43 and Appendix C. As noted below,
6 there are also linkages to propagation and developing an understanding about whether
7 passage improvements have any effect on survival of hatchery releases.

8 *4.2.5.2.3 Action Description*

9 Due to the uncertainty in knowing the type and timing of action that might be
10 implemented at Intake, there is further uncertainty in knowing what other actions might
11 be most appropriate to implement as part of the MRRP AM Plan. The preferred
12 alternative in the final EIS for Intake is to implement a bypass channel to support
13 passage of adults and free embryos. Other alternatives that were considered include
14 existing channel modifications, dam removal, as well as no action (which could be a
15 near-term outcome if a decision were delayed or implementation of the preferred
16 alternative were deferred for more than 5 years).

17 If passage improvements occur, a variety of study components would be undertaken to
18 assess the influence of fish passage improvements at Intake on the Upper River
19 population of pallid sturgeon. These components are framed around the five broad
20 monitoring questions presented above and would need to be tailored further depending
21 on the passage alternative that is eventually implemented:

- 22 ○ **Component 1 (C1):** Monitor physical conditions as well as a group of
23 telemetry-tagged adult pallid sturgeon to understand compliance and
24 effectiveness of upstream and downstream passage, as well as the specific
25 behaviors and movement of adults around Intake.
- 26 ○ **Component 2 (C2):** Track movements of telemetry-tagged adult pallid
27 sturgeon to understand their movements in the Yellowstone River, upstream of
28 the fixed telemetry stations positioned around Intake.
- 29 ○ **Component 3 (C3):** Track aggregations and spawners upstream of Intake to
30 understand whether spawning occurs.
- 31 ○ **Component 4 (C4):** Track the movement and fate of free embryos and larvae
32 downstream through Intake to understand potential impacts on mortality.
- 33 ○ **Component 5 (C5):** Post-spawn monitoring of free embryos / larvae to
34 evaluate the success of spawning and hatching by documenting the presence of
35 free embryos and natural recruitment.

36 Table 45 provides more detail around these study components. These components are
37 strongly inter-related, and require coordination across the different agencies

1 responsible for monitoring. Reclamation has the primary responsibility for monitoring
2 related to Intake Diversion Dam and the passage channel. The USACE has
3 responsibilities for monitoring to support AM of the MRRP. Component 1, 2, and 3
4 would require tracking the same group of telemetry-tagged adult pallid sturgeon as the
5 monitored sub-sample of the population in the Yellowstone River, based on a future
6 study design for passive telemetry in the Upper River (see Table 43, BQ1/L1C1 and
7 Appendix C). These study components would parallel monitoring in the Lower River in
8 response to spawning habitat creation and spawning cue flows (see Sections 4.2.6.5 and
9 4.2.6.6). Capture, implantation, and intensive passive tracking protocols developed by
10 the USGS would be used to document adult movements, passage at Intake, migration to
11 spawning sites, aggregations of adults, and spawning itself (as described in Delonay et
12 al. 2016a and other references cited therein). Component 4 would require sampling
13 embryos and determining their fate in the lower Yellowstone River (upstream of Lake
14 Sakakawea) in the same way that would be conducted in the Lower River, using a
15 sampling design that supports the broader population monitoring program, the details
16 of which have yet to be finalized (see Appendix D).

17
18 The details and integration of these study components depends on the passage
19 alternative that is eventually implemented. For instance, if a bypass channel or existing
20 channel modifications were implemented, then all study components would be
21 appropriate. However, if dam removal were implemented then components 1 and 4
22 would be more focused on monitoring river conditions at the location of Intake instead
23 of monitoring the performance of Intake's physical structures. Lastly, if fish passage
24 were not provided or if there were an extended period with no passage, then an adult
25 transplant experiment above Intake (catch and haul) could be conducted in
26 combinations with study components 2-5. If the risks from capture, handling and
27 transport are judged to be acceptable (to be discussed with the Recovery Team), then it
28 may also be beneficial to translocate a group of reproductive adults to locations
29 upstream of Intake dam prior to construction to evaluate whether spawning habitats
30 exist and successful spawning can occur. This experiment and the resulting data would
31 provide insights into the effectiveness of passage, identify biological constraints, and
32 potentially lead to other actions that might help to avoid jeopardy and move towards
33 recovery goals in the Upper River.

34

1 Table 45. Summary of the study components and related details to assess effectiveness of Intake Diversion Dam¹.

Monitoring question	More detailed monitoring questions	Monitoring details	Monitoring responsibilities
Q1. Do motivated spawners and downstream adult migrants successfully move past Intake?	<ul style="list-style-type: none"> • Q1A: Are the target physical criteria (e.g., depth and velocity) for passage of pallid sturgeon being met? • Q1B: Are the target biological criteria (e.g., number of motivated spawners moving upstream past Intake) being met? • Q1C: Are fish able to approach and navigate the bypass? • Q1D: Is the speed of upstream / downstream movement of adults unimpeded? • Q1E: Does passage lead to injury, stress, or mortality of adult pallid sturgeon migrating downstream? 	Various study designs have been proposed by the Bureau of Reclamation which differ across passage alternatives (see Reclamation 2016). These designs include monitoring of the physical criteria/conditions of the selected alternative (e.g., bypass channel, rock ramp) during a baseline period with a proposal for less intensive monitoring after a period of learning. A set of telemetry stations would also be established at strategic locations to track the upstream and downstream movement of telemetry-tagged fish at, below, and above Intake (i.e., 3–6 locations including one mile downstream, one mile upstream, and at various locations around Intake depending on the selected alternative).	Primarily the Bureau of Reclamation since this study component is focused on evaluating the effectiveness of passage at Intake. The USACE would have some responsibilities for monitoring in the first year of operation, as referenced in Reclamation (2016).
Q2. How far upstream do motivated spawners migrate?	<ul style="list-style-type: none"> • Q2A: Do spawners migrate sufficiently far upstream to provide enough drift distance to support development of free embryos? 	The location and number of fixed-station telemetry receiver sites have yet to be determined and are linked to the design of the broader telemetry network in the Upper River (see Table 43, BQ1/L1C1 and Appendix C). Once movement and spawning has been detected upstream of Intake, advection/dispersion models and in-river monitoring (Q4) would be used to estimate whether free embryos are likely to drift into Lake Sakakawea.	The USACE would install and maintain a passive telemetry network and more intensive boat-based tracking upstream of Intake.
Q3. Does successful aggregation and spawning occur?	<ul style="list-style-type: none"> • Q3A: Are spawning locations of suitable quality? • Q3B: Do spawners aggregate in sufficient numbers to initiate spawning? • Q3C: Is spawning successful? 	This study would employ a similar design as will be used to assess spawning in the Lower River (see Sections 4.2.6.5 and 4.2.6.6). Monitoring would involve tracking telemetered spawners that migrate upstream of Intake. Data collection would involve opportunistic measurements of in-river conditions as spawning aggregations and spawning occur, physical conditions at identified spawning locations, recapturing females to confirm egg release, and sampling to detect	The USACE would maintain and operate mobile telemetry gear to track spawning events.

¹ For further information please see the Final EIS and ROD for the Lower Yellowstone Intake Diversion Dam Fish Passage Project (USBOR and USACE 2016a, 2016b)

		embryos in locations immediately downstream of spawning locations.	
Q4. Do free embryos, larvae, and young-of-year successfully move downstream past Intake?	<ul style="list-style-type: none"> • Q4A: Can embryos, larval, and young-of-year sturgeon move downstream without impacts on survival (i.e., due to impingement and entrainment)? • Q4B: Are sources of impact on survival of embryos due to physical conditions /structures at Intake (i.e., over dam, through side channel, entrained in canal)? 	Strategies to monitor free embryos and larvae are broadly similar across passage alternatives (see Reclamation 2016). If upstream spawning has been confirmed and there is sufficient lead time, larval nets would be deployed at select locations in-river, near the headworks, in the main canal, and downstream of Intake to ensure larvae are successfully passing downstream.	Primarily the Bureau of Reclamation since this study component focuses on understanding the effectiveness of passage improvements at Intake.
Q5. Is recruitment successful and sufficient to meet population targets?	<ul style="list-style-type: none"> • Q5A: Does successful spawning result in recruitment? • Q5B: Is the level of recruitment sufficient to meet population targets? 	Details on locations, gear type, and effort to successfully monitor free-embryos/larvae are described in Appendix D. The intent would be to assess whether natural recruitment occurs by sampling embryos/larvae at locations downstream of the spawning site and Intake Diversion Dam and tracing genotypes to parents that spawned upstream. If natural recruitment is detected, this information would be used in the pallid sturgeon population model to evaluate how passage improvements affect population trajectories.	The USACE would monitor embryos / larvae at downstream locations in the Yellowstone River to understand whether natural recruitment is occurring and track progress towards population recovery goals.

1
2

1 4.2.5.2.4 *Objectives and Expected Benefits*

2 The ultimate objective of this study component is to assess progress towards USFWS
3 goals and objectives for pallid sturgeon (section 4.1.1) as well as recovery goals described
4 in USFWS (2014), through the population's response to improvements in fish passage at
5 Intake, and whether this action is sufficient to support natural recruitment in the Upper
6 Missouri River. More specifically, this study will provide information on upstream
7 movements of adults and downstream movement of embryos past Intake, the location of
8 adult aggregations and spawning sites, and the likelihood that free embryos will drift
9 into Lake Sakakawea. By sequentially answering the above monitoring questions,
10 decision makers will be able to better discern the biological outcomes of passage
11 improvements, leading to more timely and targeted adjustments in recovery actions (see
12 Section 4.2.5.2.7). Given a limited set of Level 3 actions in the Upper River at this time,
13 this information would also be essential for informing decisions around implementation
14 of management actions in other parts of the basin (e.g., flow, temperature, or sediment
15 manipulations at Fort Peck, drawdown of Lake Sakakawea).

16 4.2.5.2.5 *Metrics*

17 Monitoring metrics will be specific to the five study components described above. Data
18 collection will involve sampling at two spatial scales for different purposes by agencies
19 with different monitoring responsibilities: (1) monitoring by the Bureau of Reclamation
20 (Reclamation 2016) in the immediate vicinity of Intake Diversion Dam to assess the
21 effectiveness of fish passage improvements and compliance with USFWS criteria for
22 physical and biological success (see Thabault no date), and (2) monitoring by USACE
23 upstream and downstream of Intake Diversion Dam to evaluate progress towards pallid
24 sturgeon population recovery goals and avoidance of jeopardy. There will also be a need
25 to coordinate data collection around these metrics with other study components within
26 the MRRP since there are strong linkages to monitoring at other locations for other
27 actions (e.g., telemetry to assess spawning success for both passage improvements at
28 Intake in the Upper River and spawning habitat creation and spawning cue flows in the
29 Lower River). A summary of metrics by study component includes the following (also
30 listed in Appendix K):

- 31 • **Component 1 (C1):** water velocity and water depth at cross-sections within
32 structures and around Intake, timing of arrival and number of motivated spawners,
33 numbers of adults passing upstream/downstream of Intake; speed and route of adult
34 passage upstream/downstream of Intake (e.g., existing irrigation canal, bypass
35 channel, over weir), survival of adults upstream/downstream of Intake, condition of
36 upstream/downstream migrating adults (i.e., injury/stress);

- 1 • **Component 2 (C2):** number/sex of individuals, timing and distance of upstream
2 migration, genetics of spawners;
- 3 • **Component 3 (C3):** measures of fish aggregation and spawning behavior (e.g.,
4 male:female ratio), number and location of spawning sites (i.e., through
5 telemetry/acoustic video), site characteristics of spawning locations (e.g., water year
6 conditions, velocity, water temperature, suspended sediment, substrate, cross-
7 section profile), confirmation of egg release through recapture of female spawners;
- 8 • **Component 4 (C4):** number (survival) of embryos at locations immediately
9 upstream and downstream of Intake, location of downstream passage past
10 Intake/sources of mortality (e.g., over dam, through side channel, entrained),
11 number (survival) of free embryo and young-of year passing downstream of Intake;
12 and
- 13 • **Component 5 (C5):** water conditions during downstream drift of embryos,
14 numbers of embryos/free embryos collected at downstream locations on the
15 Yellowstone River, genetics of embryos, survival of free embryos calculated from
16 calibrated advection/dispersion model runs as a proportion that should be retained
17 in the free-flowing river at first feeding, rate of natural recruitment, probability of
18 population persistence over a 50-year timeframe based on projected outputs from
19 the pallid sturgeon population model.

20 4.2.5.2.6 *Experimental Design*

21 In the near term, these monitoring components would be focused on testing the
22 response of improved passage on adult spawning in the upper Yellowstone River and
23 drift of free embryos downstream, as well as compliance of the selected alternative at
24 Intake with physical and biological success criteria that have been articulated by
25 USFWS. Longer term monitoring across a broader spatial scale would be required to
26 assess the population response to passage improvements. Below we discuss some of the
27 more specific sampling design, spatial, and/or temporal contrasts related to the above
28 study components.

29 **Component 1 (C1):** As noted in Reclamation (2016), there are a variety of potential
30 passage alternatives that could be implemented at Intake. For some alternatives, it may
31 not be possible to meet physical success criteria under all flow conditions. Yet as noted
32 in Section 4.2.5.2.7, there is a need for decision makers to be able to detect failures in
33 passage structure at Intake if physical and/or biological criteria are not being met.
34 Hence, the location, timing, and duration of monitoring physical conditions at Intake
35 needs to both assess compliance with the physical and biological success criteria, as well
36 as have the ability to clarify where the passage structure might be failing and what might
37 be required to improve its design. For passage alternatives that are being considered, an
38 acoustic Doppler current profiler (ADCP) would be deployed at appropriate cross-

1 sections to monitor depth and velocity during the spawning season. The location and
2 timing of monitoring are described in Reclamation (2016) and are intended to capture
3 variation in physical and hydraulic conditions. The intention is to initially monitor
4 conditions for a baseline period (1-3 years), with effort scaled back in intermediate (3-6
5 years) and longer (6+ years) time frames.

6

7 **Components 1, 2, and 3 (C1, C2, C3):** These study components require installing
8 telemetry tags on the same group of pallid sturgeon ranging in size and reproductive
9 condition using passive telemetry protocols developed by the USGS (Delonay et al.
10 2016a and other references cited therein). Low population abundance and cost will limit
11 the number of fish that can be tagged; too small a sub-sample of individuals would limit
12 opportunities to make inferences about population-level benefits and affect the length of
13 time monitoring is required to assess the benefits of passage improvements. Tagging
14 would also require that individuals of reproductive age are not being used in the
15 propagation program, though genetic sampling would be required to trace parentage of
16 embryos sampled at downstream locations. Overall, careful consideration would need to
17 be given to decide on the appropriate number of fish tagged each year as a sub-sample
18 of the spawning population and then monitor consistent numbers from year to year (to
19 be determined through the telemetry monitoring study identified in Table 43, BQ1/L1C1
20 and Appendix C).

21

22 There will also be challenges in detecting a population level effect due to the low number
23 of individuals that can be expected to use the Yellowstone River upstream of Intake.
24 Data since 2006-2007 indicate that roughly 85 to 90% of telemetered fish in the Upper
25 River use the Yellowstone, while in 2011, a year with high flows, only 35% used the
26 Yellowstone River. On average, only 12-15% of tagged adults have been known to make
27 the long migration up to Intake, representing about 5 fish, only 1-2 of which are typically
28 female. Successful spawning requires an aggregation of more than 5 males at a single
29 location to encourage a female to spawn. Hence, there may be a need for many years of
30 monitoring (e.g., 10-15 years) to evaluate whether aggregations can occur in sufficient
31 numbers at enough locations to initiate natural recruitment. In the absence of natural
32 movement there may be a benefit of using shovelnose sturgeon to test for the
33 effectiveness of passage or to conduct more manipulative experiments with pallid
34 sturgeon to encourage upstream spawning in sufficient numbers (i.e., trap and haul).

35

36 The most reliable way to track fish is to install fixed telemetry stations at strategic
37 locations to provide spatial continuity along the Yellowstone River, with an emphasis on
38 locations from Intake to Cartersville dam, the next upstream barrier to migration (see
39 example locations in Figure 69). As noted below, finer-resolution telemetry with
40 acoustic tags, potentially 3-d systems, would also be required to provide more

1 information on habitat selection. In the Monitoring and Adaptive Management Plan for
2 the Lower Yellowstone Passage Project (Reclamation 2016), four telemetry stations are
3 proposed around Intake: one mile downstream of the passage channel, one mile
4 upstream of the diversion weir, along the passage channel, and at the headwork
5 structures.

6

7 Prior to construction it would be essential to continue consistently monitoring
8 telemetered fish to establish a pre-project baseline of spawners in spawning locations in
9 the lower Yellowstone River (below Intake). This information will provide a baseline
10 understanding about spawning in the lower Yellowstone River and the effects of passage
11 improvements at Intake. Determining whether the selected passage alternative is
12 successful would require a spatial comparison of the number of adult fish upstream and
13 downstream of Intake, which could likely be assessed within a few years. As noted
14 below, however, additional monitoring would be required over a longer timeframe to
15 determine whether aggregation and spawning occurs, embryos are detected
16 downstream, and natural recruitment is subsequently observed.

17

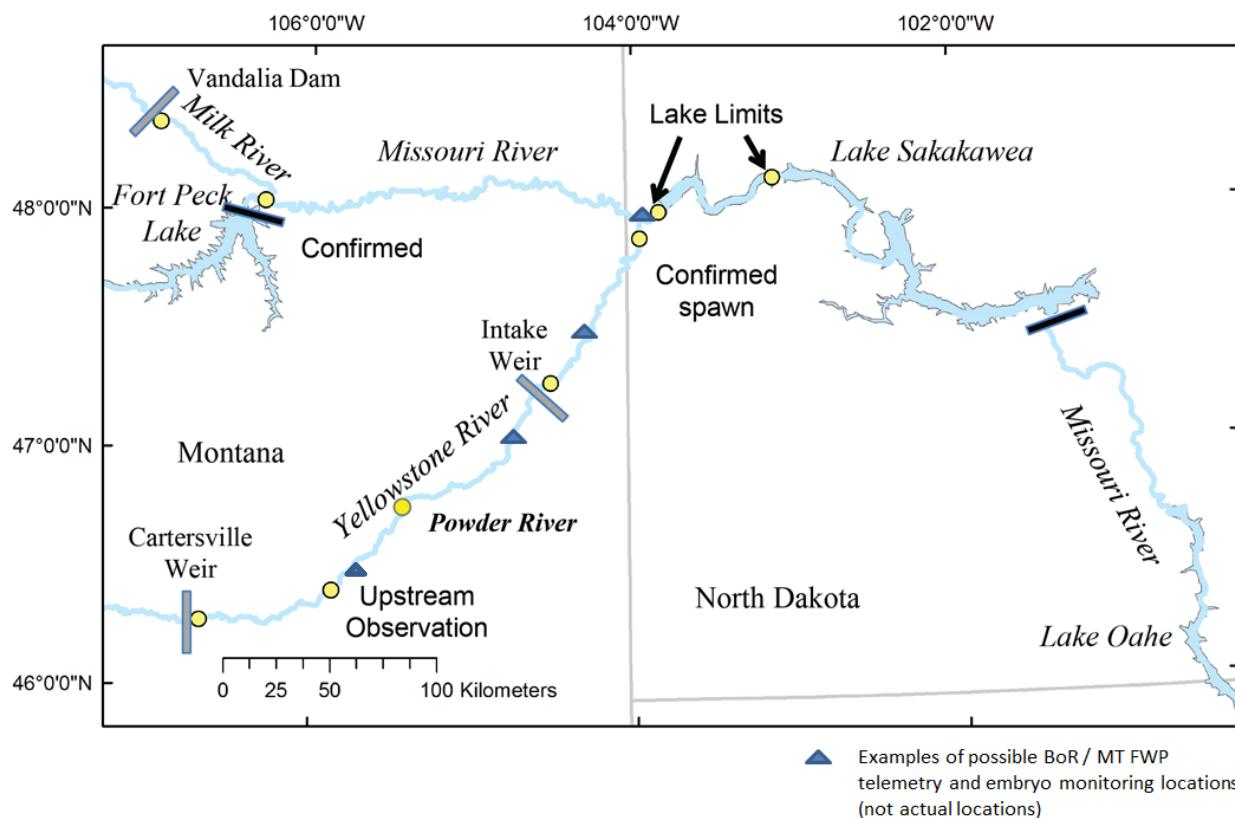

18 **Component 3 (C3):** In addition to the telemetry monitoring discussed above, another
19 consideration will be the need to monitor the physical characteristics of spawning
20 habitats once a spawning aggregation has been confirmed. This information would
21 provide important insights for understanding habitat availability and key features that
22 support spawning in both the Upper and Lower River (see Section 4.2.6.5 and 4.2.6.6).
23 Although there is some historical evidence of spawning upstream of Intake (see Figure
24 69), the location of spawning could change following passage improvements at Intake.
25 Section 4.2.5.2.5 lists the biological and habitat metrics that would be monitored at
26 those locations following sampling protocols that are referenced in Delonay et al. 2016a.
27 Multi-receiver, 3D telemetry and DIDSON (Dual Frequency Identification Sonar) video
28 would also be used to capture a spawning event. As well, fish would be recaptured to
29 determine if spawning has occurred (i.e., gravid before, no eggs after with a decrease in
30 body weight).

31

32 **Components 4 and 5 (C4 and C5):** These study components would focus on passive
33 detection of free embryos and larvae downstream of spawning events upstream of
34 Intake. In the case of monitoring at Intake, the intent would be to assess whether
35 embryos move past the structure and whether it has an impact on survival using a
36 spatial contrast in sampling, deployed at locations immediately upstream and
37 downstream of Intake when successful spawning has been documented (see
38 Reclamation 2016). To quantify embryo survival it may also help to experimentally
39 release shovelnose sturgeon embryos above Intake Dam to estimate the proportion that

1 get entrained into the irrigation ditch, and to determine whether changes in operations
2 during critical migration period can reduce the rate of entrainment.

3
4 Passive detection of free embryos and larvae would also occur in downstream locations
5 on the Yellowstone River (yet to be determined) using established sampling protocols
6 (see PSPAP in Appendix D). Since it will be difficult to acquire direct evidence of
7 recruitment to age-1 and later ages for several years, the intent in the near term would
8 be to examine the size, age, and genetics of sampled embryos associated with a
9 spawning event, alongside application of the advection-dispersion model, to assess if
10 embryos are likely to survive based on spawning location alone. Since a large number of
11 eggs (150,000 to 250,000) can be hatched over a relatively short time frame (3-4 days),
12 the sampling scheme would deploy nets over a short interval (e.g., for 10-15 minutes)
13 multiple times per day to ensure that the sampling protocol does not miss capturing
14 drifting embryos after a spawning event. Post-construction monitoring would need to
15 continue until results indicate whether or not the project has resulted in successful
16 recruitment. A determination of successful natural recruitment would take more than 5
17 years since some time is required for embryos to develop into free swimming larvae and
18 juveniles of a sufficient age/size to be sampled. However, varied success in
19 passage/spawning and low detection of adults/juveniles may lead to a mix of results and
20 a need to monitor for a longer time frame. Further analyses of these sampling challenges
21 (including statistical power analyses) should be completed as Level 1 research under Big
22 Question 5 (BQ5/L1/C3 in Table 45).

1

2 Figure 69. Locations of possible fixed telemetry locations (triangles) to monitor adult pallid sturgeon in the
 3 Yellowstone River.

4 4.2.5.2.7 Decision Criteria

5 Decision criteria guide the Technical and Implementation Teams when evaluating
 6 monitoring and other information and in developing recommendations for
 7 consideration by the agencies. Although there remains uncertainty about the alternative
 8 at Intake that is implemented, there are some consistencies to the study components
 9 that would be conducted to understand the effectiveness of passage improvements at
 10 Intake (as noted in Section 4.2.5.2.3). There are also some dependencies in answering
 11 key monitoring questions that should be evaluated in sequence to understand at which
 12 stages in the life cycle there may be a problem with passage improvements. If so, there
 13 may be additional decisions that can be implemented to support natural recruitment of
 14 juvenile pallid sturgeon and progress towards the USFWS goals and objectives for pallid
 15 sturgeon in the Missouri River (section 4.1.1), as well as recovery goals (USFWS 2014).

16 Table 46 presents the sequence of questions and decision relevance of different
 17 monitoring results, for each of the study components presented above. The effectiveness
 18 of Intake as a Level 3 action in the Upper Missouri River requires an evaluation of data
 19 to assess:

- 1 • Do motivated spawners and downstream adult migrants successfully move past
2 Intake?
- 3 • How far upstream do motivated spawners migrate?
- 4 • Does successful aggregation and spawning occur?
- 5 • Do free embryos, larvae, and young-of-year successfully move downstream past
6 Intake?
- 7 • Is recruitment successful and sufficient to meet population targets?

8 The first question requires an assessment of whether the physical and biological criteria
9 for Intake are being met and that these criteria are sufficient to support upstream
10 passage and downstream movement of different pallid sturgeon life stages (see Thabault
11 no date and Reclamation 2016). These criteria include:

- 12 • maintaining depth and velocity ranges within specified limits that depend on the
13 selected passage alternative;
- 14 • ensuring 85% of adult pallid sturgeon motivated to spawn can migrate upstream
15 during the spawning migration period (April 01-June 15) without substantial delays;
- 16 • ensuring upstream passage of juveniles occurs without negative population-level
17 effects;
- 18 • minimizing mortality of adult pallid sturgeon during downstream passage to 1%
19 during the first 10 years of project implementation; and
- 20 • monitoring of downstream passage of free embryos at the intake screens, in the
21 irrigation canal, and immediately below Intake Dam to assess mortality.

22 Decision criteria for the remaining questions are unavailable, yet need to be assessed to
23 evaluate progress towards USFWS goals of avoiding jeopardy and moving towards
24 recovery (see Table 46).

25 Successful natural recruitment would occur if data revealed that: spawners were able to
26 migrate successfully past Intake and sufficiently far upstream; successful aggregations
27 and spawning occurred; Intake provided for safe downstream passage of embryos; and
28 naturally recruited age-0 pallid sturgeon genetically linked to the spawners passing
29 Intake were detected in the lower Yellowstone River. To understand whether natural
30 recruitment is sufficient to support population recovery, more robust population
31 monitoring may be required to better quantify the benefits of passage improvements
32 and inform parameter estimates in the population model (see Appendix D). Ambiguity
33 in the results would be expected if answers to the above questions were equivocal (e.g., a
34 limited amount of successful spawning is documented or natural recruitment can only
35 be documented in 1 of 5 years). Additional monitoring would likely be required if results
36 were equivocal, since the data could not be used to defensibly reject any question.

1 Table 46 Summary of the monitoring questions for Intake and the decision relevance of different answers to these questions.

Question	Detailed questions	Decision relevance of answers to questions		
		No [or <th>Inconclusive []</th> <th>Yes [or </th>	Inconclusive []	Yes [or
Q1. Do motivated spawners and downstream adult migrants successfully move past Intake?	• Q1A: Are the target physical criteria (e.g., depth and velocity) for passage of pallid sturgeon being met?	Assess compliance with biological criteria (Q1B). If biological criteria are met, reassess physical criteria, and assess upstream movement (Q2). If biological criteria are not being met, investigate deficiencies in passage provided (Q1C-E).	Collect more data. Re-assess design of compliance monitoring. (e.g., location, frequency, and/or timing of sampling).	Assess compliance with biological criteria (Q1B). If biological criteria being met, investigate distance of upstream movement (Q2). If biological criteria not being met, re-assess physical criteria.
	• Q1B: Are the target biological criteria (e.g., number of motivated spawners moving upstream past Intake) being met?	If number of spawners moving upstream is not sufficient, investigate deficiencies of passage (Q1C-E).	Collect more data. Re-assess design of compliance monitoring (e.g., location, frequency, and/or timing of sampling).	If sufficient number of spawners move upstream, investigate distance of upstream movement (Q2).
	• Q1C: Are fish able to approach and navigate the bypass? • Q1D: Is the speed of upstream / downstream movement of adults unimpeded? • Q1E: Does passage lead to injury, stress, or mortality of adult pallid sturgeon migrating downstream?	If problems are detected, modify the passage structure to improve number of adults moving upstream/downstream. Continue to monitor compliance with biological criteria (Q1B).	Collect more data. Re-assess monitoring of behavior and movement of adults through structure (e.g., location, frequency, and/or timing of sampling).	If no problems are detected, reassess physical and biological criteria. Monitor distance of upstream movement (Q2).
Q2. How far upstream do motivated spawners migrate?	• Q2A: Do spawners migrate sufficiently far upstream to provide enough drift distance to support development of free embryos?	If migration distance is consistently insufficient, other Level 3 actions in the Upper River may be necessary.	Collect more data. Re-assess design of telemetry network (e.g., location, frequency, and/or timing of sampling).	If migration distance is sufficient, investigate success of aggregation and spawning (Q3). Consider other actions if necessary (i.e., passage at Cartersville).
Q3. Does successful aggregation and spawning occur?	• Q3A: Are spawning locations of suitable quality?	If spawning locations are unsuitable, investigate creation of spawning habitats. Continue to monitor upstream migration (Q2).	Collect more data. Re-assess monitoring of spawning locations (e.g., location, frequency, and/or timing of sampling).	If spawning locations are of suitable quality, investigate aggregations and spawning success (Q3B-C).
	• Q3B: Do spawners aggregate in sufficient numbers to initiate spawning? • Q3C: Is spawning successful?	If aggregations and/or spawning are unsuccessful, consider ways to increase success (e.g.,	Collect more data. Re-assess design of spawning occurrence	If aggregations and spawning is successful, investigate downstream movement past

		increase numbers as hatchery fish mature). Other Level 3 actions in the Upper River may be necessary.	(e.g., location, frequency, and/or timing of sampling).	Intake (Q4) and whether natural recruitment occurs (Q5).
Q4. Do free embryos, larvae, and young-of-year successfully move downstream past Intake?	• Q4A: Can embryos, larval, and young-of-year sturgeon move downstream without impacts on survival (i.e., due to impingement and entrainment)?	If Intake has impacts on survival of juveniles, investigate source of mortality (Q4B).	Collect more data. Re-assess juvenile monitoring of downstream passage at Intake (e.g., location, frequency, and/or timing of sampling).	If juvenile survival is unaffected by downstream passage through Intake, investigate whether natural recruitment occurs (Q5).
	• Q4B: Are sources of impact on survival of embryos due to physical conditions / structures at Intake (i.e., over dam, through side channel, entrained in canal)?	If impacts are not directly related to Intake, investigate other potential sources of mortality (e.g., predators).	Collect more data. Re-assess juvenile monitoring of downstream passage at Intake (e.g., location, frequency, and/or timing of sampling).	Modify structures at Intake to improve downstream passage of juveniles. Re-assess physical criteria for downstream passage at Intake. Continue to monitor impacts on downstream passage (Q4A).
Q5. Is recruitment successful and sufficient to meet population targets?	• Q5A: Does successful spawning result in recruitment?	Investigate sources of potential limitation in recruitment (e.g., distance upstream, passage at Cartersville, number of spawners, quality of spawning habitats, passage efficiency at Intake). Take action to address potential limitations.	Collect more data. Re-assess design of juvenile monitoring (e.g., location, frequency, and/or timing of sampling).	Test genetics of embryos to parentage of upstream spawners. Apply population model. Assess whether natural recruitment is sufficient to meet population targets (Q5B).
	• Q5B: Is the level of recruitment sufficient to meet population targets (95% probability of persistence over a 50-year period)?	Investigate opportunities to enhance natural recruitment. Take action. Continue to monitor (Q1-5).	Collect more data. Re-assess design of juvenile monitoring and/or population model (e.g., location, frequency, and/or timing of sampling).	Maintain beneficial actions to ensure success in achieving recovery goals. Continue to monitor (Q1-5).

1 4.2.5.2.8 *Level 3 Contingent Actions*

2 The fundamental scientific uncertainty related to improved fish passage at Intake is
3 whether reproductive adults will find passage around or over Intake Dam and migrate a
4 sufficient distance up-stream for spawning. Resolution of this uncertainty will have a
5 profound effect on the ability to predict whether recruitment is possible in the Upper
6 River. Robust monitoring and assessment should resolve this uncertainty. In the event
7 that Intake is not successful, other uncertainties become more important. For instance,
8 one of those uncertainties relates to biological departures from purely passive transport
9 of free embryos. If free embryos progressively develop the ability to move themselves
10 out of the current or to slow dispersal by interacting with benthic bedforms, then
11 advection/dispersion calculations will overestimate dispersal distance. In that scenario,
12 the other management actions being considered are more likely to have the potential to
13 support natural recruitment. The Missouri River Pallid Sturgeon Free Embryo Drift
14 Study, undertaken in June and July 2016 (and summarized in section 4.1.2) will provide
15 insights into this uncertainty.

16 As illustrated by the decision trees on information needs that emerged from the EA (see
17 Section 4.1.2.5), a determination of the effect of fish passage at Intake on natural
18 recruitment has a strong influence on the exploration of other Level 3 actions on the
19 Upper Missouri River. For instance, if spawning occurs at locations far enough
20 upstream in the Yellowstone River so that free embryos have sufficient distance to allow
21 for transition to first feeding upstream of Lake Sakakawea, then other Level 3 actions on
22 the Upper Missouri River may not be necessary to recover the subpopulation. In this
23 situation, successful wild recruitment would be required at a level that would increase
24 and sustain population abundance over a sufficient time frame. Alternatively, if Intake
25 fails to result in sufficient natural recruitment, or if results are equivocal (e.g.,
26 recruitment does not occur with sufficient frequency), then other Level 3 actions might
27 be required. These actions could include decreases in flows from Fort Peck to decrease
28 downstream transport rates, increases in temperatures from Fort Peck to increase
29 developmental rates, drawdown of Lake Sakakawea to increase available dispersal
30 distance, or some combination thereof. Implementation of these other actions would
31 require evidence from related Level 1 and Level 2 studies to suggest that some
32 combination of actions would improve survival to first feeding in the Upper River (see
33 study components related to Big Question 5 in Table 43).

34 The contingent nature of Upper Missouri River actions on the success of Intake also
35 affects the timing of other Level 1 science components and Level 2 actions described in
36 Appendix C and summarized in Table 43 (see discussion of learning strategies in Section
37 4.2.3). The schedule in Figure 69 assumes that various Level 1 activities will occur
38 concurrently, exploring key hypotheses sooner in the absence of definitive results on the

1 biological performance of Intake (i.e., parallel staging). This implementation schedule
2 reflects ongoing and planned research to address hypoxia, interstitial hiding and drift
3 hypotheses in this reach that will have been executed prior to significant monitoring of
4 the Intake passage project.

5 **4.2.6 Details on Level 3 Actions (and associated Level 2 components) for Lower
6 Missouri River**

7 Figure 64 (in section 4.1) presented a decision tree for possible actions to ensure
8 survival and recovery of pallid sturgeon in the Lower Missouri River. A more detailed
9 decision tree for the Lower Missouri is found in Appendix F. The following potential
10 Level 3 actions emerge from these decision trees: population augmentation, creation of
11 interception and rearing complexes (IRCs), creation of spawning habitat, and
12 manipulation of flows and/or temperatures. The remainder of section 4.2.6 discusses
13 each of these actions (with the exception of manipulation of temperatures, which is not
14 yet a candidate Level 3 action, and is discussed for Levels 1 and 2 in Section 4.2.4 and
15 Appendix C).

16 **4.2.6.1 Level 2 Studies - Population Augmentation**

17 **4.2.6.1.1 Introduction**

18 Section 4.2.5.1.1 above provides a summary of current hatchery practices and the
19 decision making processes for propagation, led by the Recovery Team and involving
20 other entities. Those decision making processes will ultimately determine whether there
21 is a need to change the number, biomass, size, age, genetics or location of hatchery fish
22 that are stocked, as well as potential changes to hatchery practices. There remains
23 considerable uncertainty about what actions will be recommended by the Recovery
24 Team. It is important that whatever actions are recommended, that they be rigorously
25 designed, implemented, monitored and evaluated, consistent with AM principles. To
26 illustrate such a rigorous approach, this section describes an example Level 2
27 management experiment which could be undertaken to improve population
28 augmentation in the Lower Missouri River (section 4.2.6.1.3). This is only one example
29 of many possible actions which could emerge from the Recovery Team, and the actual
30 experimental design will need to be tailored to the selected actions. Section 4.2.6.2
31 describes future augmentation actions at Level 3 and Level 4, which could potentially be
32 altered as a result of Level 2 management experiments. As the Recovery Team and other
33 entities converge on a propagation strategy, a similar structured approach should be
34 applied to the selected preferred actions.

1 4.2.6.1.2 *Hypotheses*

2 The following hypotheses are relevant to this action¹:

- 3 • H20. Stocking at optimal size classes and in optimal numbers will increase growth
4 rates and survival of exogenously feeding larvae and juveniles.
- 5 • H21. Stocking with appropriate parentage and genetic diversity² will result in
6 increased survival of embryos, free embryos, exogenously feeding larvae, and
7 juveniles.

8 Testing these overall hypotheses will require a nested set of more detailed hypotheses
9 that are structured to be amenable to specific statistical and modeling analyses, and will
10 need to build on Level 1 analyses of existing data. The term “optimal numbers” in H20
11 could mean a change up or down from current practices to match current carrying
12 capacity. Genetics (part of H21) is an issue of increasing concern in the Missouri River.
13 More detailed hypotheses related to genetics (and associated metrics) will need to be
14 developed as part of the ongoing work on a Basin-wide Stocking and Augmentation
15 Plan.

16 4.2.6.1.3 Action Description

17 Propagation has been ongoing for a long time at Level 3 to increase the abundance of
18 pallid sturgeon in the wild. Unlike some other actions where Level 2 studies are required
19 before undertaking Level 3 actions (e.g., spawning cue flows), the purpose of Level 2
20 studies of propagation is to better understand how well current methods of propagation
21 have been working, and to explore alternative approaches that might better avoid
22 jeopardy.

23 Level 2 components are envisioned to be field-based experiments that will vary size at
24 stocking and assess differential survival. These Level 2 activities may not be necessary to
25 decide among facilities/operations options if the retrospective evidence that's reviewed
26 and modelled at Level 1 under Big Question 6 (components BQ6/L1/C2 and C3 in Table
27 44) is sufficiently robust. Moving to Level 2 would be recommended if the data and
28 models indicate a high sensitivity of cost and survival to size at stocking, and more
29 precise parameters for the relationships are needed.

¹ The wording of these hypotheses is exactly the same as propagation hypotheses H8 and H9 described under section 4.2.5.1.2, but have different numbers to distinguish the lower river hypotheses from the upper river hypotheses.

² Genetic diversity refers to variability in genotypes comparable to the unaltered, wild population. The assumption is that maintenance of the appropriate genetic diversity will result in increased fitness of individuals and the population. Further research is required to define performance measures and targets for genetic diversity.

1 This example Level 2 management experiment would involve stocking fish at variable
2 sizes (representing variable hatchery costs), and/or manipulating other hatchery factors
3 (such as the genetics of stocked fish to meet specified objectives for identified metrics)
4 while keeping all other factors as constant as possible. Such management changes have
5 occurred in the past. The intent of this description is to illustrate a well-designed
6 approach which maximizes the ability to detect the signal from implemented actions,
7 while controlling for the noise created by year to year variability in flow and variability
8 amongst hatcheries. Genetics is another factor which could affect the outcomes of this
9 management experiment, and has been included as a covariate to help explain
10 outcomes. If this Level 2 experiment were to proceed (which depends on both the
11 strategy developed by the Recovery Team and the availability of sufficient hatchery fish
12 of the appropriate size), it could be a planned comparison of survival rates and fish
13 metrics between releases as fingerlings or yearlings, accounting for variation in
14 outcomes due to both hatchery differences and the type of water year.

15 4.2.6.1.4 Objectives and Expected Benefits

16 The objective of this Level 2 management experiment is to make long term
17 improvements in the cost-effectiveness of propagation practices, or to confirm that
18 current practices are the most appropriate for maintaining and recovering pallid
19 sturgeon populations. Many of the design principles could be applied to other types of
20 actions.

21 4.2.6.1.5 Metrics

22 Metrics would include: estimated number and survival probabilities for stocked pallid
23 sturgeon by stocked size and age, hatchery of origin; fish condition; genetics; and water
24 year conditions (as additional covariates to help explain survival rates). Metrics for
25 genetics have not yet been determined, but will be discussed in the development of the
26 Basin-wide Stocking and Augmentation Plan. Candidate metrics might include such
27 measures as the mean observed heterozygosity for multiple polymorphic markers, mean
28 relatedness among individuals, allelic richness, and effective population size (Richard
29 Lance, Environmental Genomics and Conservation Genetics Laboratory, USACOE, pers.
30 comm.).

31 4.2.6.1.6 Experimental Design

32 **Overall design.** This management experiment would need to take place over a number
33 of years and a number of hatcheries to separate out three factors: the local effects of
34 hatcheries (some tend to have higher quality fish than others), the practices applied in
35 each hatchery (e.g., age at release), and the particular circumstances in each water year.

- 1 The design will need to take place in the context of the overall propagation strategy
2 developed by the Recovery Team, and consider various practical constraints (e.g., the
3 availability of a sufficient number of hatchery fish, the implications of the experiment
4 for stocking targets and hatchery operations, genetic factors, size constraints on
5 tagging). These practical constraints will inevitably (and appropriately) lead to
6 modifications to the example design described here. A common experimental design for
7 these type of studies is a staggered-entry design similar to the staircase design of
8 Walters et al., 1988, Figure 70; staircase designs are also discussed by Roni et al. 2012
9 and Bennett et al 2016. For example, hatchery A would start an alternative hatchery
10 management practice in year t1+1; hatchery B would start the alternative practice in
11 year t1+2; and hatchery C would remain a control, applying current practices. The years
12 prior to implementing an alternative hatchery management practice at each hatchery act
13 as controls, to be compared with the alternative treatment. Monitoring after release
14 occurs via the population monitoring program where recaptured fish have their tags
15 read and fish metrics determined. If changes in the genetics of hatchery fish become
16 part of the alternative management practices under consideration in the development of
17 a Basin-wide Stocking and Augmentation Plan, then part of the experimental design
18 would involve tracking metrics of population genetics over time, and also relative to
19 some baseline or target values. Such baseline or target values might be obtainable from
20 historical samples, and by sampling wild populations (Richard Lance, Environmental
21 Genomics and Conservation Genetics Laboratory, USACE pers. comm.).
- 22 Results from Level 1 studies and expert opinion would be used to determine the contrast
23 of interest, e.g. releasing fingerlings vs releasing yearlings. Retrospective information
24 will be needed to estimate year-specific effects (e.g., does a wet year impact survival
25 rates different than a dry year?), and hatchery effects (e.g., how different are survival
26 rates for similar fish released in the same year in two different hatcheries?). This
27 retrospective information and the size of effect to be detected between the release
28 groups is then used in a power analysis to determine combinations of how many fish are
29 needed to be released; how many hatcheries are needed; how many years of releases;
30 and how many years of monitoring are needed to reliably detect this effect. Additional
31 fish/hatcheries/years may be added to mitigate the impact of unforeseen impacts of
32 disease or disaster at a hatchery. Planning for implementing such an experiment at
33 hatcheries would also occur (e.g., is there sufficient broodstock, tanks, and water?).

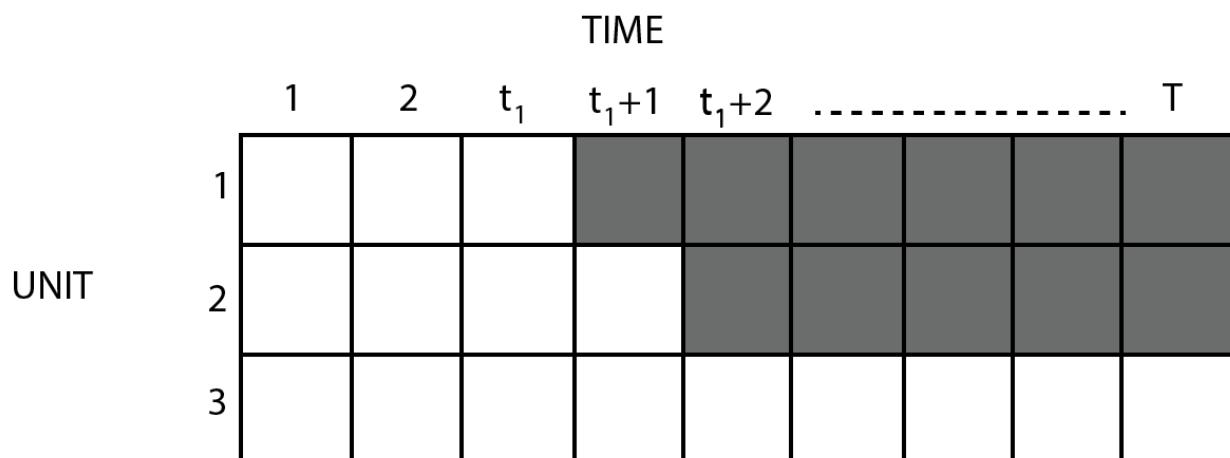

Figure 70. Illustration of a staircase design. Treatments are staged so as to avoid confounding of treatment effects and year effects. Unit 1 is treated in year t_1+1 ; unit 2 is treated in year t_1+2 ; and unit 3 remains untreated. Adapted from Walters et al. 1998.

Released fish will either be individually tagged with PIT-tags (if large enough) or using other marking methods (for smaller fish). Parental genotyping will be done so that a recaptured fish without a PIT-tag can be identified back to the year class and type of release before a PIT-tag is inserted.

Length of the Experiment. The number of years that are required for the implementation of this study should follow the recommendations of the power analyses. It is difficult to determine the time needed for such an experiment, but robustness consideration imply that at least 3 different years of releases over at least 3 hatcheries with an additional 5 years of monitoring may be needed for a total of 8-10 years for the study.

Data analyses. The study results will use the database created as part of the Level 1 retrospective studies under BQ6/L1/C2 and BQ6/L1/C3 (see Table 44).

There are a variety of methods which could be used to analyze the data. Variants of a Cormack-Jolly-Seber (CJS) model could be used to estimate survival of the release groups using the multiple recapture occasions using mark recapture software such as Program MARK. Because monitoring methods have changed over time and will continue to be improved (see Appendix D), more complex statistical models may also be required (e.g., the robust-design model or hierarchical-Bayesian models to allow for information sharing among sparse datasets).

Standard ANOVA methods can be used to evaluate differences in fish metrics across release groups. Power analyses can be used to determine the yearly samples required to determine a change in survival.

1 Evaluation of standard versus alternative hatchery practices could be based on the
2 survival estimates produced by the CJS model, and whether there are statistical
3 differences in survival. The collaborative population model could be used to project the
4 population consequences of differences in survival probabilities. Because **differences**
5 in survival are of interest, it may not be necessary to fully model emigration from the
6 system as long as it is roughly equal across all release groups. Data will accumulate over
7 time. Interim analyses will be conducted each year after the monitoring for the year is
8 complete.

9 4.2.6.1.7 Decision Criteria

10 Decision criteria guide the Technical and Implementation Teams when evaluating
11 monitoring and other information and in developing recommendations for
12 consideration by the agencies. Interim analyses may indicate that the experiment
13 demonstrates a biologically significant benefit (as determined by simulations of long
14 term outcomes) with a high likelihood. This could be used along with other lines of
15 evidence to accelerate changes in hatcheries going forward. The criteria used to
16 determine biological benefit will require further discussion among the Recovery Team,
17 USFWS and other entities. A weight of evidence approach, using multiple criteria based
18 on the above-described field metrics, and model simulations of consequences, is
19 preferred. The Lower Missouri Framework (USFWS and USACOE 2015) mentions two
20 possible criteria related to propagation: the number of adult pallid sturgeon in each
21 management unit (target of 5000), and the threat of extirpation over 50 years (target of
22 less than 5%). Criteria for more specific objectives will be presented in the Basin-wide
23 Stocking and Augmentation Plan for pallid sturgeon.

24 4.2.6.1.8 Uncertainties and contingency plans

25 Practical constraints on the study design were summarized above. Uncertainties in the
26 design of this study (and possible contingency plans) include:

- 27 • *Insufficient fish to run experiment.* Required sample sizes may be too large given the
28 number of broodstock that are available and reproductively ready. The experiment
29 can still be run with the smaller sample size, but it will require more years of
30 monitoring to obtain sufficient recaptures.
- 31 • *Hatchery rearing problems.* For example, disease may remove a hatchery from
32 production. This will reduce the sample size, power, and require additional years of
33 monitoring.
- 34 • *Amount of monitoring needed.* The proposed population monitoring plan may not
35 be sufficient (both spatially and intensity) for evaluating this experiment under

1 realistic numbers of releases and time frame. This would require more intensive
 2 monitoring.

- 3 • *Survival estimates are not sufficiently precise to be useful.* If survival estimates fail
 4 to show reliable inferences (e.g., very wide confidence intervals), an evaluation of the
 5 cause is needed. Despite the planned power analysis, the actual survival rates could
 6 be different than used during planning, indicating that sample sizes were
 7 inadequate.
- 8 • *Environmental conditions change from those used in planning.* Environmental
 9 conditions may affect survival in unforeseen ways and the experiment may not be a
 10 proper reflection of longer-term conditions. For example, a mini-drought may occur
 11 during the experiment. Dealing with this uncertainty would require extending the
 12 experiment for a longer period of time.

13 4.2.6.2 Level 3 studies – Population Augmentation

14 4.2.6.2.1 Action Description

15 Population augmentation (stocking) of pallid sturgeon is already taking place at a level
 16 having a measurable effect on the population (i.e., Level 3), and will continue. While
 17 population augmentation is *necessary* for recovery of the pallid sturgeon, by itself it is
 18 not *sufficient* as the ESA requires a self-sustaining population. Augmentation can help
 19 severely depleted populations recover numbers of individuals needed to evaluate what
 20 works and what doesn't in recovering the population. Additionally, some concurrent
 21 Level 1 and Level 2 components are proposed to develop information to improve on the
 22 Level 3 implementation (see Figure 71 for an approximate schedule).

Stocking																	

23 Figure 71. Preliminary timeline of actions related to propagation, as proposed by the USFWS and USACE
 24 (2015). Activities and timeline are likely to be revised in response to the new Basin-wide Stocking and
 25 Augmentation Plan for pallid sturgeon. Arrows represent flexibility in the timing of implementation.

26 Supplementation actions will be closely coordinated with the new Basin-wide Stocking
 27 and Augmentation Plan for pallid sturgeon being developed by the Pallid Recovery
 28 Team because of important concerns related to fish health/disease, genetics, stocking
 29 size, stocking practices, etc. Once the Plan is developed, the target values in Table 42
 30 will be adjusted to reflect the role of the MRRP in meeting plan objectives. The target
 31 values in the table may best be represented by running averages in addition to or rather
 32 33

1 than annual minimums or maximums. It is important that the Basin-wide Stocking and
2 Augmentation Plan rely upon the collaborative population model being developed as
3 part of the EA and AM Plan (and in support of the recovery plan). This model can
4 incorporate multiple alternative hypotheses and is specially designed for the MRRP.
5 Other modeling efforts, should they arise, may be viewed as additional lines of evidence,
6 though the preferred approach is to explore alternative hypotheses within a single
7 modeling framework.

8 4.2.6.2.2 Objectives

9 The stocking rate and target number of fish stocked is intended to ensure a 95%
10 probability of persistence for the species over a 50-year period, and at least 5000 adult
11 pallid sturgeon per management unit (USFWS and USACE 2015). Short-term objectives
12 are to increase the number of adult pallid sturgeon in the lower Missouri River. Long-
13 term objectives are to reduce and eventually eliminate the need for supplemental
14 stocking by demonstrated wild recruitment at a level sufficient to meet the fundamental
15 objectives and associated sub-objectives (section 4.1.1). Criteria for more specific
16 objectives will be presented in the Basin-wide Stocking and Augmentation Plan. The
17 targets per management unit may be adjusted over time by the USFWS in response to
18 increased knowledge about carrying capacity, effective population size, and other
19 factors.

20 In addition to the above primary objectives, more specific, means objectives for
21 propagation have been identified and include increased fitness and genetic diversity of
22 released fish (to better match natural genetic variation in the wild population, as
23 discussed in section 4.2.6.1), improved brood stock handling, and adjusting hatchery
24 capacity. Some of these efforts are being addressed through Level 1 and 2 studies.
25 Further work is required to define metrics for genetic diversity.

26 A key uncertainty of the evaluation process is whether the population model reflects
27 reality, and has scientifically defensible estimates of abundance and survival for
28 different life stages. If the population model does not reflect reality, the performance
29 measures generated by the model will not be meaningful.

30 Figure 71 shows the timing of implementation of actions related to propagation as
31 suggested by USFWS and USACE (2015). Deviations from that implementation plan will
32 be documented. Implementation at Level 3 is to begin immediately (i.e. continue from
33 present, with recommended changes in propagation from the Basin-wide Stocking and
34 Augmentation Plan) following issuance of the ROD, but there is no specific timeframe
35 identified for transition to a Level 4 action.

1 4.2.6.2.3 Metrics

2 The metric for reporting and assessing stocking rates will be yearling equivalents;
3 performance measures will be based on a three-year running average of annual yearling
4 equivalents. Other metrics include: number and survival rates (to age-0, age-1¹, and
5 juvenile stage) for stocked pallid sturgeon by stocked size, hatchery of origin, and
6 condition; catch rates of adult pallid sturgeon; measures of fitness including population
7 genetics; condition factor; levels of disease; and simulations of the benefits of
8 propagation using field-estimated survival rates (e.g., probability of quasi extinction,
9 instantaneous growth rates, and sensitivity measures under various scenarios and
10 parameterizations of the collaborative model, including alternative hypotheses and
11 functional relationships). Metrics are subject to adjustment upon coordination with the
12 Recovery Team on the new Basin-wide Stocking and Augmentation Plan for pallid
13 sturgeon. Population monitoring and modeling approaches are described in Appendix
14 D. A more detailed list of metrics is provided in Appendix K.

15 4.2.6.2.4 Experimental Design

16 The hatchery strategy developed through Level 2 studies of propagation (section
17 4.2.6.1.3) will be implemented for a number of years, with monitoring of the above-
18 described metrics. Estimated survival rates through this Level 3 implementation will be
19 compared to those expected from the Level 2 studies. Evaluations of fish survival rates
20 and rearing practices may lead towards revision of the Level 3 action. As natural
21 recruitment improves, it may be necessary to adjust both stocking levels and stocking
22 strategies.

¹ Age-0 fish become age-1 fish on January 1st

1 4.2.6.2.5 Decision Criteria

2 Decision criteria guide the Technical and Implementation Teams when evaluating
3 monitoring and other information and in developing recommendations for
4 consideration by the agencies. Population augmentation may be halted when population
5 monitoring demonstrates that a self-sustaining population in excess of 5000 adult fish
6 exists in each management unit, when the threat of extirpation is less than 5 percent in
7 50 years, or as based on new criteria introduced through the Pallid Sturgeon Recovery
8 Plan by the Recovery Team (see USFWS 2014). These criteria could include other
9 considerations, such as genetics, fish community health (carrying capacity), habitat
10 availability and hybridization.

11 Adjustments to the number of fish and their age structure will be based on the results of
12 population modeling and sensitivity analyses using the most up-to-date version of the
13 model available each year. Until the model is sufficiently robust to meet this need, a
14 target of 5000 adult pallid sturgeon in each management unit will serve to guide
15 stocking rates, when the threat of extirpation is less than 5 percent in 50 years, or as
16 based on new criteria introduced through the Pallid Sturgeon Recovery Plan.

17 Triggers for Moving to Higher Implementation Level: No clear transition from Level 3
18 to Level 4 exists; implementation at Level 3 will continue until such time as
19 supplemental stocking is no longer required.

20 Trigger for abandoning population augmentation actions: Population augmentation
21 may be halted when population monitoring demonstrates that a self-sustaining
22 population in excess of 5000 adult fish exists in each management unit, when the threat
23 of extirpation is less than 5 percent in 50 years, or as based on new criteria introduced
24 through the Basin-wide Stocking and Augmentation Plan. These triggers should be
25 evaluated within the pallid sturgeon population model framework, with recognition of
26 the carrying capacity of different sections of the river.

27 Triggers for adjusting augmentation practices to optimize fitness or genetic diversity:
28 Hatchery practices need to be evaluated to assess the impact on fish health. Measures of
29 genetic diversity must be considered.

30 4.2.6.2.6 *Level 3 Contingent Actions*

31 Contingency plans for artificial propagation are limited to those associated with the
32 secondary objectives; adjustments to the propagation program will focus on achieving
33 the necessary fitness and genetic diversity.

1 4.2.6.3 *Interception and Rearing Complexes (IRCs)*

2 4.2.6.3.1 *Hypotheses*

3 The following hypotheses (discussed in the EA) are relevant to this action:

- 4 • H17. Re-engineering of channel morphology in selected reaches will increase channel
5 complexity and bioenergetic conditions to increase prey density (invertebrates and
6 native prey fish) for exogenously feeding larvae and juveniles.
- 7 • H18. Re-engineering of channel morphology will increase channel complexity and
8 minimize bioenergetic requirements for resting and foraging of exogenously feeding
9 larvae and juveniles.
- 10 • H19. Re-engineering of channel morphology in selected reaches will increase
11 channel complexity and serve specifically to intercept and retain drifting free
12 embryos in areas with sufficient prey for first feeding and for growth through
13 juvenile stages.

14 The EA (Jacobson et al. 2016a) found that there was theoretical support for all of these
15 hypotheses, and from hydrodynamic models, but that data were equivocal as to whether
16 IRC habitat was a limiting factor (Table 38). Testing these hypotheses requires an
17 experimental design with high statistical power, discussed further in section 4.2.6.5.6 on
18 Experimental Design. The Lower Missouri River Pallid Sturgeon Framework (USFWS
19 and USACE 2015; pg. 11), posed some more detailed hypotheses that are somewhat
20 more amenable to field tests:

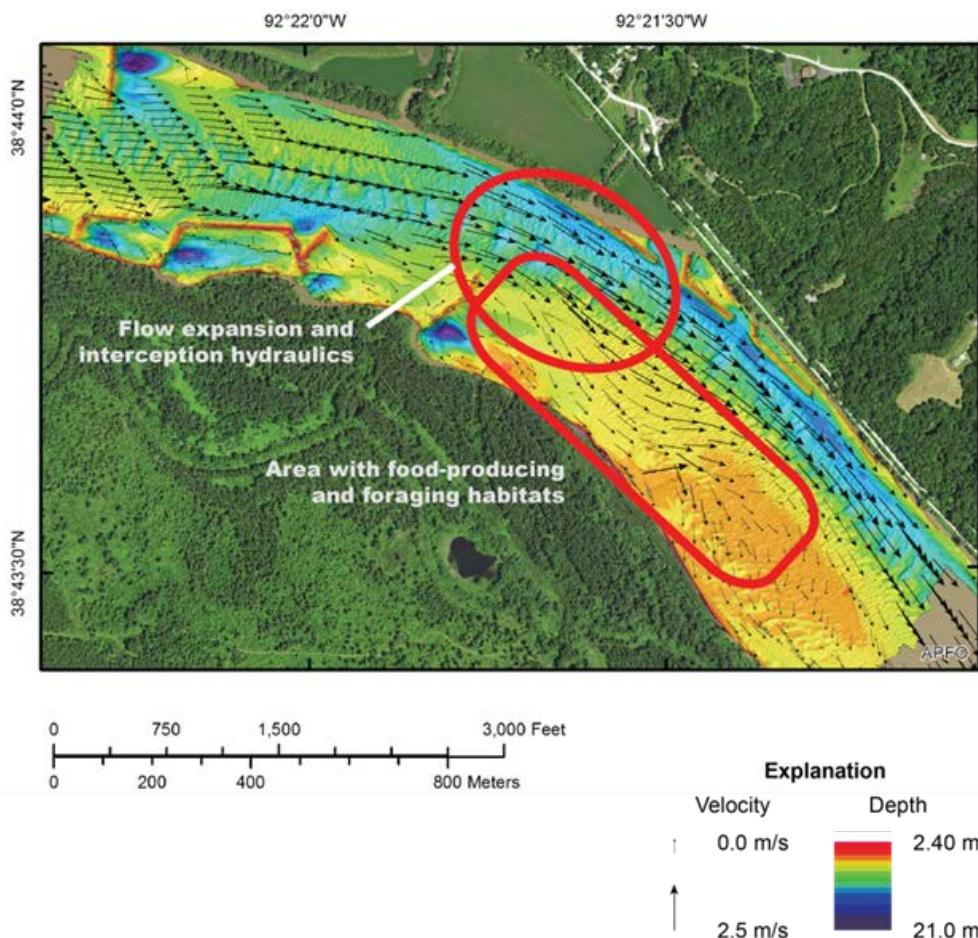

- 21 • *Interception habitat* - Improved or increased interception of drifting free embryos
22 from the thalweg and transport to supportive channel-margin habitats will increase
23 survival of free embryos to exogenously feeding age-0.
- 24 • *Food production habitat* - A lack of food limits survival of age-0 pallid sturgeon.
25 [Chironomids are particularly important to benthic-feeding, age-0 pallid sturgeon.]
- 26 • *Foraging habitat* - An increase in availability and quality of foraging habitat will
27 increase survival of age-0 pallid sturgeon.

28 4.2.6.3.2 *Action Description*

29 Interception and rearing complexes (IRCs) are areas that meet the functional definitions
30 laid out in the EA Integrative Report. For the purpose of establishing targets and
31 measuring progress, the physical definitions of IRCs are currently identified as follows:
32 1) food-producing habitat occurs where velocity is less than 0.08 m/s, 2) foraging
33 habitat is defined as areas with 0.5 – 0.7 m/s velocity and 1-3 m depth, and 3)
34 interception habitat has been qualitatively described as zones of the river where

1 hydraulic conditions allow free embryos to exit the channel thalweg (Figure 72). A
2 functional IRC exists where the juxtaposition of the described habitats is such that all
3 three functions are performed and collectively contribute to survival to age-1. These
4 specifications could be adjusted as warranted based on monitoring and evaluation, or
5 new information (see Section 6.2.5), regarding observed utilization of different habitats
6 by age-0 pallid sturgeon. Research is continuing on conditions that create interception
7 hydraulics. Effective interception hydraulics seem to occur where flow expands
8 downstream from a wing dike followed by a relatively long section of river without wing
9 dikes (Figure 72). Creating effective interception hydraulics on the Lower Missouri River
10 may require only modest changes to wing-dike geometries.

11

12

13 Figure 72 Concept of an interception-rearing complex near river mile 162. Flow expansion is shown by
14 modeled current velocity and direction (arrows) angled away from the channel and towards the right
15 descending bank.

1 The biologically optimal size of an IRC is not known. The maximum size of individual
2 IRCs is constrained by both channel width and typical bend length. Individual IRCs
3 adjacent to the main channel were estimated to range from 80 to 260 acres in size for
4 the MRRMP-EIS. Constructed side-channel chutes can also provide IRC functions and
5 would likely be somewhat larger. IRCs would be designed and constructed to maintain
6 the navigation channel and minimize any changes to flood heights.
7

8 The availability of food-producing and foraging habitats varies with flow, as does the
9 local hydraulic field at any location (and hence the potential for interception and
10 retention). Consequently, IRC habitat is flow-dependent and time-variant and can be
11 affected by both mechanical manipulations of river geometry and flow management
12 actions. For the timeframe addressed by the MRRMP-EIS (approximately 15 years), flow
13 management will not be required to meet any IRC targets associated with Level 3 unless
14 information developed during Level 1 and Level 2 implementation unequivocally
15 demonstrates the need for flow manipulation. Because flow manipulations will not be
16 assessed under the current actions for Level 3 (Table 40), additional NEPA analysis of
17 those actions would be required before implementing changes to flows to improve the
18 performance of IRCs.

19 Level 1 and 2 activities associated with IRCs focus on: 1) the need for additional IRC
20 habitat, 2) refining the relationship between the habitat components, flow (utilizing
21 current operations), and the biological requirements of each habitat type, 3) the needed
22 habitat characteristics and their spatial and temporal distributions, and 4) determining
23 the effectiveness of various mechanical activities and the potential for flow management
24 actions to contribute to future IRC needs. A proposed sequencing for actions associated
25 with IRCs, developed by USFWS and USACOE (2015), is shown in Figure 73. To the
26 extent possible and where appropriate, Level 1 and 2 activities will incorporate habitat
27 projects which have already been completed. Although the habitat focus has changed
28 from Shallow Water Habitat (SWH), there is likely much that can be learned from
29 existing SWH projects, and it is expected that many SWH projects may address one or
30 more functional components of IRC (as described in Section 4.2.6.4.2).

31 Level 3 actions include physical manipulation of habitats and structures on the Missouri
32 River to create or improve areas having hydraulic conditions to intercept drifting free
33 embryos combined with food-producing habitats and foraging habitats. Actions might
34 be directed at one or any combination of the three components of IRCs. Examples
35 include adjustments to navigation training or bank stabilization structures, channel
36 widening, floodplain modifications or other adjustments to channel geometry,
37 placement of structures to encourage development of needed habitat or habitat
38 complexity, chute development or adjustments to existing chutes, etc. In addition to

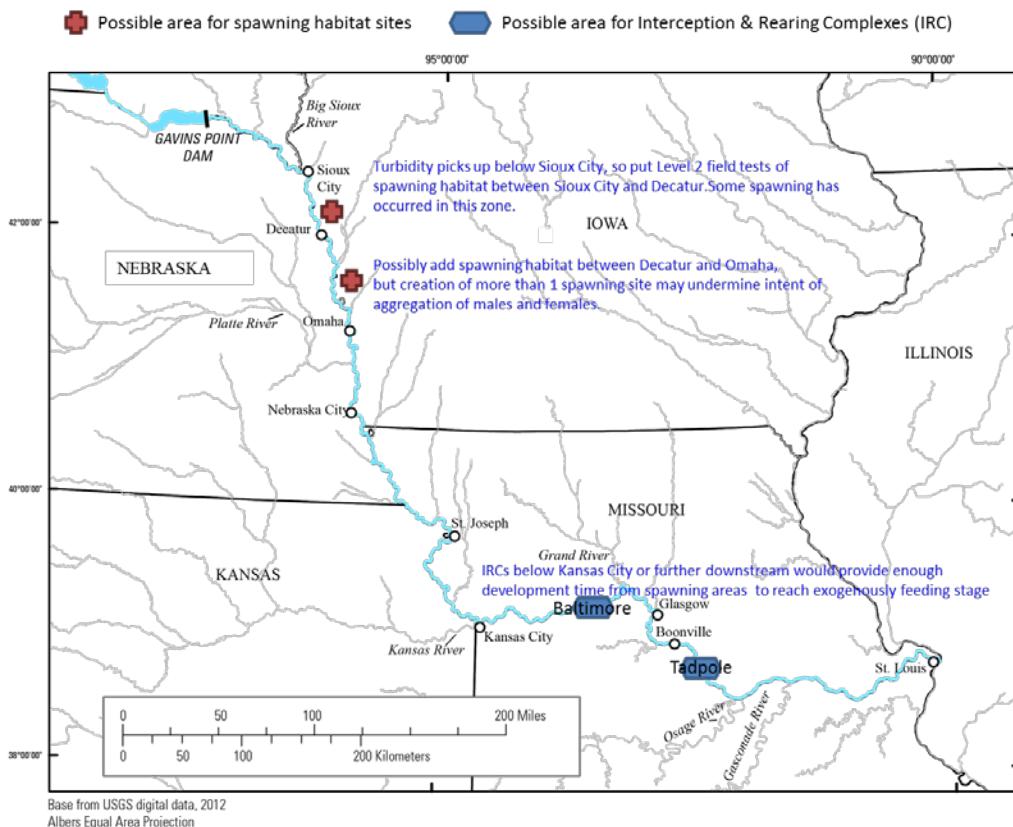

1 development of functional IRCs, management actions will be aimed at ensuring
 2 availability of IRC habitats over a wide range of flows as well as the necessary spatial
 3 characteristics (distribution, concentration, proportions, etc.,) on the lower Missouri
 4 River such that interception, food production, and foraging are not preventing the
 5 achievement of the pallid sturgeon fundamental objectives. Increases in the amount of
 6 food-producing habitat should help to recover apparent declines in fish condition (draft
 7 report by Randall et al. 2016), as discussed in section 4.1.2.4. The timeframe for the
 8 implementation of Level 3 actions is shown in Figure 73. Deviations from that
 9 implementation plan will be documented.

11 **Figure 73. Current timeline for IRC action Implementation.** Revised from USFWS and USACOE (2015) to reflect
 12 preferred alternative and current targets in Table 42.

13 The targeted longitudinal distribution of IRCs will be influenced by biological needs as
 14 outlined in the EA and supported by results of larval drift modeling as well as other
 15 practical considerations. It is anticipated that most IRCs will be created downstream
 16 from the Platte River (RM 595), with others below Kansas City to promote sufficient
 17 time for embryos to mature into the larval form during the passive drift phase. This
 18 assumption (based on current scientific understanding) will be tested and reviewed
 19 through Level 1 science efforts during the design phase, using all available information
 20 (particularly empirical observations of the distribution of embryos and larvae coupled
 21 with improved drift-dispersal models), and evaluating the potential for interception and
 22 recruitment upstream of the Kansas River. Currently proposed locations of IRCs are
 23 shown on the map in Figure 74, together with the rationale for those locations. The
 24 strategy for site selection will be based on considerations of both maximizing survival of
 25 exogenously feeding larvae and maximizing learning, according to the experimental
 26 design described in section 4.2.6.3.4 Experimental Design, and taking into account the
 27 variability in channel conditions. Projects with potential to quickly reduce uncertainties
 28 will be emphasized to the extent practicable. New IRC habitat resulting from both Level
 29 2 and Level 3 actions that meets the IRC criteria will be counted as contributing to the
 30 targets for Level 3, as described in section 4.2.6.3.5 Metrics and section 4.2.6.3.6
 31 Decision Criteria . Level 3 actions and outcomes are focused on helping to understand
 32 and describe future Level 4 actions and targets.

2

3 Figure 74. Possible locations of new spawning habitats (red symbols), and Interception and Rearing Complexes
 4 (IRCs; blue symbols). The general rationale for these general locations is shown on the map in blue text, with
 5 further details in the text of this section.

6 Long-term (Level 4) targets will be based on the outcomes of Level 2 and Level 3
 7 management experiments, and the integration of multiple metrics on physical habitat
 8 and biological performance.. The USFWS (2016) established Level 2 targets for IRCs
 9 (Table 42; Stage 2) based on two methods: 1) the historical rate of implementation of
 10 Shallow Water Habitats (SWH) which was approximately 260 acres per year, converted
 11 into roughly 33,000 acre-days per year of suitable habitat; and 2) a model-based
 12 estimate of the increased amount of suitable food and foraging habitat (in acre-days per
 13 year) at two planned IRC sites (Searcy and Baltimore), which cumulatively equal about
 14 30,000 acre-days per year. These two different methods generated an estimate of the
 15 amount of IRC habitat to be constructed each year during Stage 2 of IRC habitat
 16 development (33,000 acre-days/year; Table 42), to be supplemented by the
 17 refurbishment of SWH into IRCs (described in section 4.2.6.4). Stage 2 will provide

1 insight on the amount of IRC habitat required at Stage 3 / Level 3; Table 42 proposes
2 66,000 acre-days/year.

3 The growth period for larval and juvenile pallid sturgeon in the lower Missouri River is
4 generally considered to occur from May (hatch) through October, though there can be
5 considerable variability, with hatching potentially occurring as early as March, and
6 apparent growth (at least in age-1 shovelnose sturgeon) occurring over the following
7 winter. Improving our understanding of the timing of growth in age-0 pallid sturgeon,
8 and the relationships between growth and other variables (e.g., temperature, flow and
9 river geometry) will be one of the priorities of Level 1 work under Big Question 3 (food
10 and forage), and hypotheses H17, H18 and H19.

11 *4.2.6.3.3 Objectives*

12 The primary objectives are to: promote the interception of drifting free embryos and
13 age-0 larvae; increase food production and effective foraging for age-0 pallid sturgeon;
14 increase survival probabilities to age-1; and ultimately increase the probability of
15 population survival and recovery in the Lower Missouri River. From a risk avoidance
16 perspective, it's important to ensure that creation of IRC habitats has a net positive
17 effect (e.g., does not reduce the availability of other important habitat types or limit
18 recruitment in the lower Missouri River, either locally or systemically). Secondary
19 objectives are to make progress toward the targeted amount and distribution of IRC
20 habitats, and to ensure that human considerations are protected. The creation of
21 spawning habitat and IRC habitats will be planned in an integrated manner, using
22 experimental designs that reveal the degree to which each of these habitats may be
23 limiting recruitment to age-1.

24 *4.2.6.3.4 Experimental Design*

25 The following principles are important for the iterative development of the experimental
26 design and monitoring protocol (building on the general principles described in
27 Appendix G):

- 28 • Develop biologically significant effect sizes for each of the IRC decision criteria listed
29 below in sections 4.2.6.2.6 and 4.6.
30 • Determine acceptable risks of false positives (falsely detecting a benefit of IRC
31 habitats when no benefit actually occurred) and false negatives (not detecting a real
32 benefit); now completed (Appendix E);
33 • If possible, use past data and possibly intensive pilot sampling to gain insight into
34 spatial and temporal variability in the relative abundance of age-0 pallid and

- shovelnose sturgeon within different habitat types, and how relative abundance varies over time and river conditions (variation over time described in Appendix E);
- Conduct statistical power analyses to determine how false positives and false negatives vary with sampling effort, number of IRC and reference sites, and the number of years of monitoring. The power analysis in Appendix E (Figure E4) indicates that acceptable statistical power (near 80%) is generally achievable for an effect size of 75% or higher (the increase in CPUE), 7 to 12 treatment-control pairs, and 7-15 years of monitoring.;
 - Use the information from steps 1-4 to refine both the experimental design and existing monitoring protocols (e.g., improving the protocol described in HAMP SOP 2015, and making it more consistent with the robust population monitoring strategy described in Appendix D). A stratified random approach could be used to guide sampling efforts throughout the habitat classification hierarchy to avoid extensive oversampling in habitats where age-0 sturgeon (possible indicator is a size ≤ 109 mm, though other length-age relationships exist) are not likely to occur, while still ensuring that all habitats are sampled. The monitoring protocol should however recognize that the spatial distribution of age-0 fish can vary considerably with flow; the locations in which age-0 fish are found tend to be correlated with current velocity. For example, age-0 sturgeon were found clustered in near shore and other seemingly protected habitat types during periods of high flow in 2010 and 2011, but were not commonly observed in these habitat types during periods of normal flow (Ridenour et al. 2012). The draft monitoring plan for IRCs in Appendix E considered the above issues, and applies a stratified random sampling approach.
 - Development of stocking and sampling strategies which can provide estimates of age-0 survival (e.g., stocking of pallid sturgeon with known genetics at a few days old, estimating survival through mark-recapture)
- The design in Appendix E envisions both treatment (IRC) sites and control sites. Control sites should be: representative of areas currently used by age-0 sturgeon, independent of the effects of IRC creation (e.g., it's better to have control sites upstream of treatment sites), in generally similar habitat categories as those used for IRCs, and accepted as providing a fair reference point for estimating the IRC treatment effect on various metrics (described below). In developing designs for IRC sites, different configurations of IRC habitat within a site can be modeled using the particle tracking analysis to determine the best configuration for interception of free embryos.
- The choice of experimental design used to assess whether the interception of age-0 pallid sturgeon increased depends on the quality, variability and quantity of existing data on catch per unit effort (CPUE) and the anticipated time for IRC modifications to show an impact following the 2-year period of construction (T. Gemeinhardt,

1 pers.comm.). Some sites identified as IRC sites may have pre-construction data (e.g.,
2 Tadpole site has 2014 and 2015 data – see Appendix E); however, other sites may not.
3 For those sites where existing data are present, the analysis could take the form of a
4 Before-After (BA) or Before-After-Control-Impact (BACI) design. It is possible to create
5 several IRC sites with a single control site as this is a simple modification of the BACI
6 design. However, a key attribute of a BA or BACI design is that the impact is immediate.
7 If the impact is not immediate, which would be expected with IRCs due to geomorphic
8 and biological changes over time, then the staircase design (Walters et al, 1998, Roni et
9 al. 2012) is preferable. Site-to-site variability is not important in BA/BACI/Staircase
10 designs as site effects cancel out when the same site is repeatedly measured over time.
11 Differences in the responses of sites to year to year changes (site- year interaction) add
12 noise to the signal from IRC sites, as explained in Appendix E. The draft monitoring
13 plan in Appendix E assumes a staircase design for both statistical and logistical reasons.

14 Practical consideration of the time required to construct IRC sites also favors a staircase
15 design. Since IRC sites will not be created all at once (construction is currently
16 anticipated to occur over a 7-year period, Appendix E), the staircase design might be
17 useful because all IRC sites would not have to be created in a single year, and interactive
18 effects with time (e.g., water years) can be detected. Power will increase over time as
19 more IRC sites are constructed. The staircase design requires at least one control site,
20 though the current design assumes 12 IRC sites and 12 control sites (Appendix E). Once
21 an IRC is deemed to be effective, it is possible to stop monitoring that IRC site and move
22 field crews to other sites. It will be important to ensure (to the greatest degree possible)
23 that multiple IRC sites are considered to be independent of one another, as well as
24 independent of control sites. Measuring covariates, which might be able to account for a
25 lack of independence, will also be important.

26 The design described in Appendix E assumes that the construction of IRC sites will not
27 impact either the control sites, or the pre-construction condition of future IRC sites.
28 Strategies to remove such potential confounding include locating control sites upstream
29 of IRC sites, and staging the spatial implementation of IRC sites in a manner that
30 minimizes potential confounding effects.

31 Staircase designs usually look for changes in mean, but they can be readily adapted to
32 detect changes in trends. For example, a change in trend could be detected by
33 comparing the slope of a regression line with a breakpoint at the date of the restoration
34 activity.

35 The draft monitoring plan (Appendix E) includes the following classes of response
36 variables:

- 1 • stratified random sampling of age-0 pallid sturgeon to generate CPUE (catch per
2 unit effort) at the IRC site level;
- 3 • length-frequency distributions at the IRC site level (increased retention and growth
4 in IRCs should cause this distribution to shift to the right compared to control
5 areas), rolled up to the project scale;
- 6 • other fitness variables of individual fish (e.g., condition, mass, % of empty/full
7 stomachs, lipid content, genetics), rolled up to the site scale;
- 8 • hydroacoustic measurements of hydraulic conditions at IRC treatment bends, both
9 pre- and post-construction, and Missouri River mainstem control bends, used to
10 estimate the amount of suitable habitat before and after construction, and to develop
11 hydrodynamic models of the depth and velocity within surveyed reaches;
- 12 • measurements of water depth and velocity; and
- 13 • predictive models of CPUE based on physical covariates, as well as the length of time
14 that an IRC site has existed, and its location.

15 Another consideration is how to treat multiple samples at each site during a year, which
16 may vary for different questions. Depending on the assumption of site closure multiple
17 samples can be handled in an Occupancy or N -mixture model.

18 The power analyses in Appendix E have been helpful in determining the extent of
19 monitoring and sampling intensity at IRC and control sites required to observe an effect
20 on the interception, growth and survival of age-0 sturgeon – including the number of
21 trawls per site, total trawls per year, and the number of years before / after that are
22 needed to detect a certain sized change in CPUE. Sampling information at multiple sites
23 and over multiple years can be used to improve the accuracy of the power analyses in
24 Appendix E, as more years of data will improve estimates of the process (natural)
25 variability and sampling variability in the system. Experimental releases of hatchery-
26 reared, first-feeding pallid sturgeon larvae could be a Level 1 tool-building action used to
27 improve statistical power.

28 Variation might be reduced, or interpretation might be aided, with suitable covariates
29 such as an index of the number of successful spawning events in that year. Adjustments
30 can be made for the actual number of spawning fish each year as opposed to treating
31 this as a ‘random year effect’ in the analysis. One would expect higher CPUE in IRC
32 areas in years when many eggs are released, all else being equal. Measuring egg
33 production (though difficult and really only feasible for telemetered fish) would be
34 helpful because egg production could be related to many factors, including both
35 management actions (e.g., spawning cue flows and the creation of spawning habitats)
36 and natural factors (e.g., the number of females in a reproductive state, natural spatial
37 and temporal variability in hydrology, abundance of predators). An index of spawning

1 success, as well as relevant flow indices, could be used as covariates in the analysis of
2 response variables to explain some of the year-to-year variation seen. The results may be
3 confounded by changes elsewhere in the system, (e.g., modifications to increase
4 spawning success may lead to an increase in CPUE even if there were no benefit from
5 the IRC work); an index of spawning success can help to reduce such confounding.

6 Some possible adjustments and refinements to the above experimental design might
7 include:

- 8 • **Trawl efficiency.** The Missouri River is a big moving river, and a challenging place
9 to sample fish. Only a small portion of the available habitat is sampled with each
10 pass of a trawl net. It would be very valuable to review past PSPAP and HAMP data
11 sets in which multiple trawls were run in approximately the same location to
12 estimate capture efficiency.
- 13 • **Residence time.** It would be valuable to get an estimate of residency time in IRC
14 complexes, possibly using 2D models, or mark-release and recapture of some of the
15 fish. Given the current capture rate, this experiment may not currently be feasible.
16 Improvements in sampling gear might make it more feasible to measure residence
17 time using mark-release methods, but changes to sampling gear must be
18 implemented gradually, as described below.
- 19 • **Gear efficiency changing over time.** If CPUE is the response variable, then it is
20 assumed that changes in CPUE are an index to changes in the underlying abundance
21 rather than an artifact of detection efficiency in the gear. A similar concern exists if
22 presence/absence is used. If gear is to be changed, then both sets of gear should be
23 run in parallel for at least two years to estimate the calibration between the two types
24 of gear. Various approaches should be considered to account for the effects of gear
25 efficiency and to improve the signal to noise ratio in the data: apply occupancy
26 models to estimate detection probabilities; do extensive training of field crews on
27 boat and net deployment methods to minimize variability within and among
28 sampling crews; perform repeat sampling to estimate variability among sampling
29 crews; and measure covariates that may be correlated with gear efficiency (e.g.,
30 velocity, turbidity, temperature).
- 31 • **Periodic resurveys of IRCs.** Re-surveys will be used to update hydrodynamic
32 models as geomorphology evolves, and will indicate whether IRCs are physically
33 sustainable. Hydrodynamic models will also provide insights into the role of the flow
34 regime in providing IRC habitats.

35 *4.2.6.3.5 Metrics*

36 The means objectives by which the USACE will be evaluated in meeting their obligations
37 under the BiOp are based on the net increase in “effective” acreage of IRC habitat (in

1 acre-days/yr) listed in Table 42. “Effective” acreage is determined by integrating the
2 developed or available IRC habitat with mean daily flows for May through October,
3 expressed as acre-days. These dates correspond with the period of growth for pallid
4 sturgeon ($T > 13^{\circ}$ C). IRC habitat occurs where foraging habitat is collocated with or
5 proximal to and downstream of food-producing habitat, and is intersected with
6 hydraulic conditions that would promote interception and retention of free embryos
7 drifting in the channel (typically in June). Habitat metrics are based on measures of
8 depths, velocities, and substrate, including mean and variance, and potentially
9 complemented with metrics of spatial complexity like diversity indices, patch shape, and
10 patch connectivity. The algorithm for calculating IRC habitat might weight the
11 hydrograph in June higher because of the importance of first feeding to survival.
12 Distribution will be evaluated as deviation from a target distribution.

13 Calculation of effective acreage will require implementation of 2-dimensional
14 computational hydrodynamic modeling at each IRC reach and at each control reach. The
15 hydrodynamic models will be compiled, calibrated, and validated using accepted
16 engineering standards for data collection and model simulation. The models will be run
17 to simulate distributions of depths and velocities over at least 20 increments of
18 discharge ranging from 90% daily exceedance to 10% daily exceedance. The outputs of
19 the models will be integrated in geographic information systems (GIS) to evaluate the
20 areas of depths and velocities that meet the prevailing definitions of IRC food-producing
21 and foraging habitats that exist at each incremental discharge (Figure 75). The present
22 definitions of food-producing and foraging habitats overlap in part with SWH (Figure
23 75), but food-producing habitat can be substantially deeper and foraging habitat is both
24 deeper and faster. The physical criteria describing IRCs are provided in section
25 4.2.6.3.2, Action Description. Additional metrics may be calculated in the GIS to explore
26 more habitat affinities and patch dynamics.

27 This evaluation step yields area of habitats as a function of discharge. The daily time
28 series of discharges in the reach (either modeled as in the EA or actual discharges
29 measured at nearby stream flow gaging stations) are then used to calculate how much
30 habitat is available, on average, for each day during the growing season, yielding acre-
31 days. Acre-days of habitat will usually be evaluated as average acre-days per year over
32 some number of years. This process provides flexibility to change habitat and growing-
33 season definitions as new information is developed, or possibly to weight certain critical
34 time periods more strongly in the calculation.

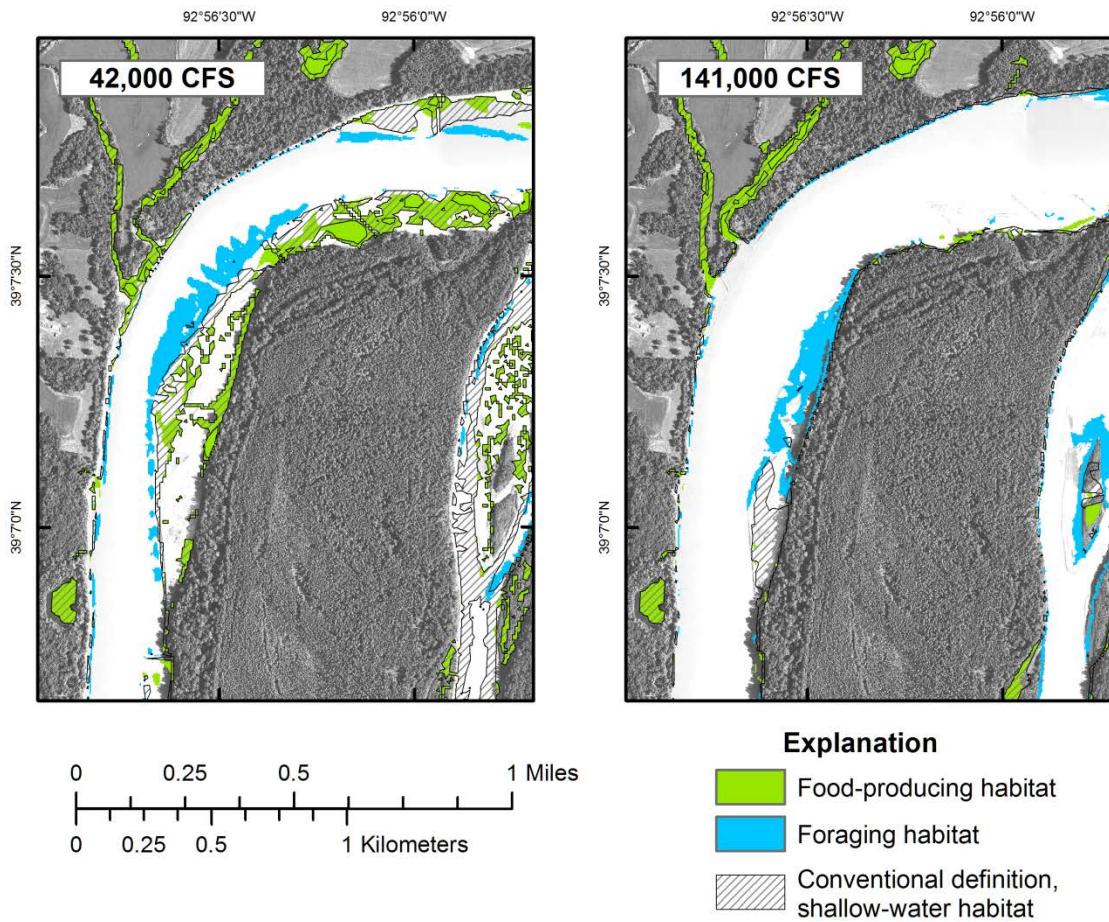

Figure 75 Maps of food-producing and foraging habitats modeled with a hydrodynamic model, river mile 219, Lower Missouri River, at two discharges. Food-producing and foraging habitats are two components of IRCs; conventionally defined shallow-water habitats are shown for comparison. Left side: Habitats at discharge of 42,000 cubic feet per second (cfs). Right side: Habitats at discharge of 141,000 cfs.

Performance of IRC actions will also be based on a subset of metrics addressing the primary objectives outlined above. The effectiveness of projects in promoting interception will be based primarily on CPUE of age-0 sturgeon at project (pre- and post-implementation) and reference sites, as described in Appendix E. Effectiveness in terms of food production will be based on production of food per unit area, survival and indicators of starvation or impending death of age-0 pallid sturgeon (percentages of empty/full stomachs; lipid content). Effectiveness in terms of foraging will be based on gut content and survival of age-0 pallid sturgeon with consideration for bioenergetics requirements of age-0 pallid sturgeon, and possibly the use of bioenergetics models. Survival rates of hatchery-reared first-feeding pallid sturgeon larvae released in the Missouri River may serve as a metric for all three IRC elements. Further Level 1 work is required to determine how mark-recapture techniques could be used to estimate survival rates of released hatchery larvae at various scales (i.e., within IRCs, in the

- 1 thalweg, across multiple IRCs, to age-1). Hatchery origin or parentage will also be of
2 interest, and may help to explain variability in abundance across hatcheries or
3 genotypes.
- 4 These various performance measures will provide multiple lines of evidence for
5 evaluating the habitat and biological benefits of IRCs. Research will explore alternative
6 ways in which these multiple performance measures could be integrated for making
7 decisions on the various phases of development of IRCs (described in Table 42 and
8 USFWS (2016)).

9 *4.2.6.3.6 Decision Criteria*

- 10 Decision criteria guide the Technical and Implementation Teams when evaluating
11 monitoring and other information and in developing recommendations for
12 consideration by the agencies. The targets for implementation (Table 42) afford a
13 straight-forward measure of compliance with the means objectives for IRCs at Level 3.
14 Net increases in habitat will be computed on an annual basis. The intention is to permit
15 flexibility to address needs while promoting learning through Level 2 actions and to
16 address programmatic requirements related to pallid sturgeon. Performance relative to
17 targets will be assessed using a running average of annual lift in effective acre-days of
18 IRC habitat (described above in section 4.2.6.3.5). Acceptable performance is meeting or
19 exceeding the targets in Table 42 based on a three-year running average for at least 4 of
20 every 5 years (80% success rate). Level 3 / Stage 3 targets could be revised based on the
21 outcome of actions at Level 2 / Stage 2.
- 22 Additional decision criteria for prioritized Level 1 and Level 2 studies are listed above in
23 Table 44 (with all L1 and L2 studies listed in Appendix C), and below in Table 53 for
24 Level 2/3 studies. If experimental results in Level 2 studies fail to demonstrate an
25 increase in key metrics relative to control areas and pre-treatment conditions, there are
26 several potential responses depending on syntheses of all lines of evidence: IRC designs
27 may need to be adjusted to be more effective; the hypothesis may need to be refined; the
28 hypothesis should be moved into set of the reserve hypotheses; or the hypothesis should
29 be abandoned. If the experimental results support the hypothesis that channel
30 reconfigurations can provide increased food-producing and foraging functional habitats,
31 and increase pallid sturgeon condition, then the decision would be to move toward Level
32 3 implementation. The four stages of development of IRCs proposed by the USFWS are
33 described in USFWS (2016) and summarized in Table 42.
- 34 Triggers for Moving to Higher Implementation Level: The decision to move from Level 3
35 to full implementation at Level 4 will be based on a systematic relationship between
36 IRCs and increases in growth and survival of age-0 sturgeon that permits modeling of

1 the needed scope of IRC implementation to meet the fundamental objectives. This
2 judgment should be based on the strength and replicability of functional relationships
3 between abiotic habitat variables describing food and forage habitats, and growth and
4 survival of age-0 sturgeon. In addition, the need for supplemental flow management at
5 Level 3 or 4 would be based on the availability of sound functional relationships
6 between flow conditions, IRC habitat, and growth and survival of age-0 sturgeon.

7 Timeframes: The timeframes for implementation of IRC habitat work are described in
8 USFWS (2016) and summarized in Table 42.

9 *4.2.6.3.7 Level 3 Contingent Actions*

10 Contingency plans for IRCs are mainly associated with the secondary objectives (e.g.,
11 structure manipulations will not adversely affect navigation); however, adjustments to
12 the targets, habitat criteria, methods, etc. might be required if performance fails to meet
13 expectations. Analyses of performance across multiple water years and multiple IRC
14 sites may reveal flow management strategies that enhance the performance of IRCs.

15 *4.2.6.4 Interception and Rearing Complexes (IRCs) via Modification of Existing Shallow
16 Water Habitat (SWH) Projects*

17 The 2003 BiOp presents a reasonable and prudent alternative (RPA) that contains
18 requirements for the restoration of SWH in the channelized portion of the Missouri
19 River. According to the 2003 BiOp, SWH may be restored through flow management,
20 increasing the top width of the channel (top-width widening), restoring chutes and side
21 channels, manipulation of summer flows, or combinations thereof (USFWS 2000,
22 2003). Modification of in-channel structures, top-width widening, and creation of
23 chutes and backwaters are SWH restoration measures that have been implemented
24 (USACE 2014). Table 47 provides the numbers, locations and types of SWH
25 construction actions through 2014 (USACE 2014).

26

27

28

29

Total # of Actions	1,697	354	36	63	20	3	39	14

¹actions include dike notching, type B notching, rootless dikes, revetment notches, and bank notches.

²actions include chevron construction and other similar actions

4.2.6.4.1 Hypotheses

Hypotheses 17 to 19, identified in section 4.2.6.3.1 (and discussed in the EA) are relevant to this action. The EA (Jacobson et al. 2016a) found theoretical support for all of these previously referenced hypotheses, and they are further supported by hydrodynamic modeling, but the data were equivocal as to whether IRC habitat was a limiting factor (Table 38). Testing these hypotheses will require a nested set of more detailed hypotheses structured for statistical and modeling analyses, as discussed further in section 4.2.6.4.4 on Experimental Design. Modification of existing SWH projects to test this subset of hypotheses may be more cost-effective compared to building new IRC projects and thereby permit earlier assessments of project performance and corresponding species response. The action-related hypothesis for this action ($\text{HSWH} \rightarrow \text{IRC}$) is as follows:

HSWH \rightarrow IRC: A subset of Shallow Water Habitat projects can be successfully converted into effective IRC habitats, providing suitable interception, food production and foraging habitats for exogenously feeding larvae and juveniles, which result in higher abundances, stronger growth and better survival of age-0 pallid sturgeon.

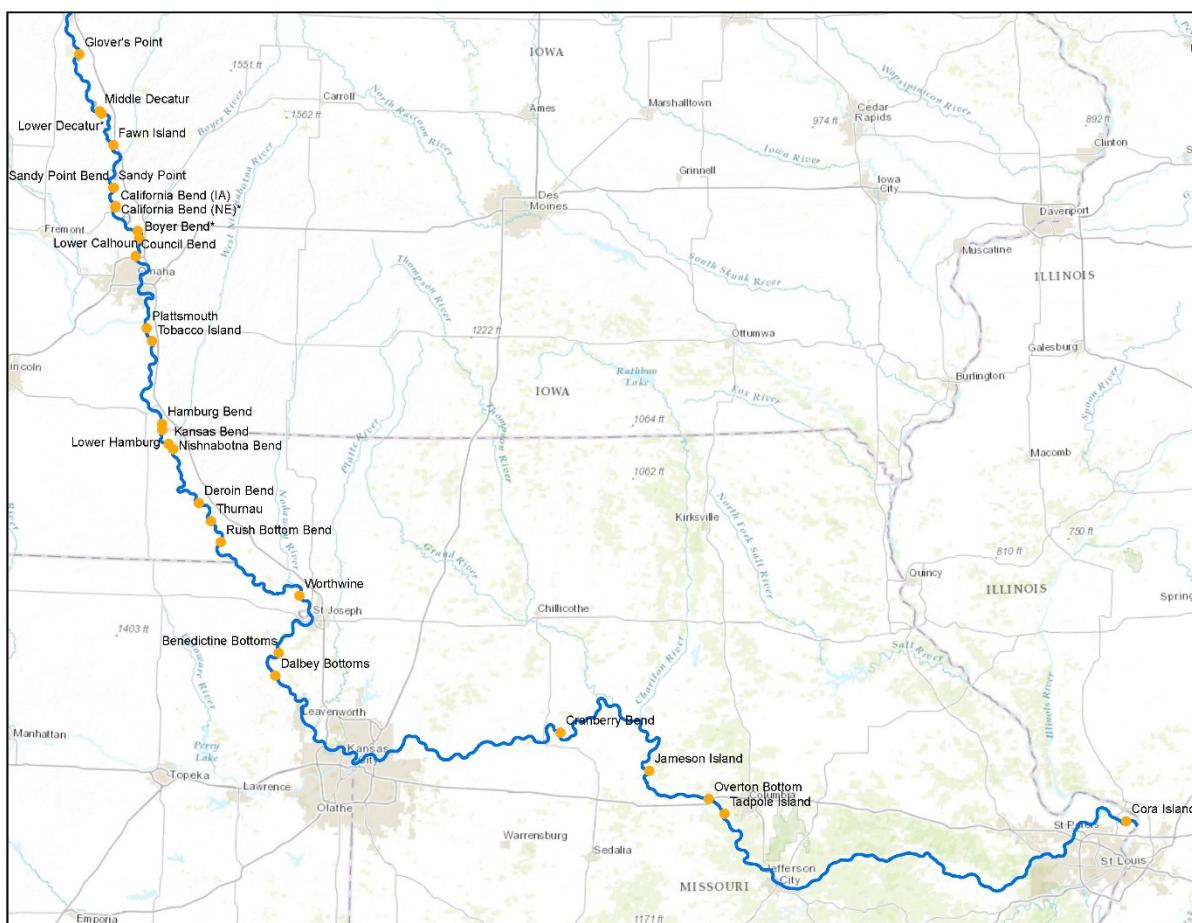

4.2.6.4.2 Action Description

IRCs are areas that meet the functional definitions laid out in the EA Integrative Report (Jacobson et al. 2016a). While the proposed criteria for food-producing and foraging

- 1 habitat components of IRCs are narrower than the previous definition of SWH,
2 significant overlap in the depths and velocities of the three habitat types exist, so
3 existing SWH projects can be modified to provide IRC habitat. A functional IRC exists
4 where the juxtaposition of the described habitats is such that all three functions are
5 performed and collectively contribute to survival to age-1, which is similar to the
6 intended design of many chute projects. There can be a significant time lag, however,
7 between chute construction and the development of desired habitat conditions. In
8 naturally-functioning chutes and side channels, it is common for sediment to be
9 deposited in the entrance and extend downstream. Sedimentation in the chute
10 contributes to reduced velocities and additional deposition within the chute that may
11 limit benthic fish access to the chute. As this process proceeds, the depth, morphology,
12 and velocities in the chute evolve, leading to habitat diversity. Habitat diversity may
13 similarly evolve through widening and lateral migration of the channel if conditions
14 allow it to erode. In some cases, chutes also have the potential to develop excessive
15 depths, higher than desired velocities, and minimal habitat diversity, which could
16 require post-construction modifications including inlet and grade control structures,
17 structures to promote meandering, structures to promote local scouring, etc. to achieve
18 the desired benefits.
- 19 The availability of food-producing and foraging habitats within existing SWH projects,
20 specifically chutes, varies with flow and the chute morphology. The location of a chute
21 entrance within a river bend and the configuration and elevation of control structures
22 can influence the ability of chutes to intercept drifting free embryos (and sediment).
23 Consequently, IRC habitat within chutes is both flow-dependent and time-variant and
24 can potentially be improved by both mechanical manipulations of river geometry and
25 flow-management actions. See section 4.2.6.3.2 for more discussion regarding the
26 utilization of flow management to reach level 3 IRC targets.

1 Level 1 and 2 activities associated with the modification of SWH projects to become
 2 well-functioning IRCs focus on: 1) defining the need for additional IRC habitat in
 3 different river sections, and how much is required, 2) refining existing empirical
 4 relationships among habitat attributes, flow (utilizing current operations), channel
 5 morphology, and observed occupancy by age-0 fish, 3) assessing the spatial and
 6 temporal distribution of desired habitat attributes, and 4) determining the feasibility of
 7 various mechanical and flow-management actions to reconfigure existing SWH projects
 8 into functional IRCs. The general timeline for actions to assess and refurbish SWH
 9 projects is shown in Figure 73. Level 1 and 2 activities will incorporate habitat projects
 10 that have already been completed. Although the focus has changed from SWH to IRCs,
 11 much can be learned from existing SWH projects and it is expected that many SWH
 12 projects may address one or more functional components of IRCs.

13 For discussions on Level 3 and 4 IRC activities see 4.2.6.3.2.

14

15 Figure 76. Existing chute locations that may be available for modification to provide IRC habitats.

1 *4.2.6.4.3 Objectives*

2 The primary objectives of modifying existing SWH sites to provide IRC habitat are the
3 same as the objectives identified for IRCS in section 4.2.6.3.3. Significant increases in
4 IRC habitat could be achieved by modifying non-functional or underperforming chute
5 projects. Because in many cases they are allowed to erode and migrate laterally, chutes
6 provide a set of attributes and functions not found in other mainstem SWH projects.
7 Chutes have higher potential to deliver large wood, increase retention of wood, and
8 develop point bars that promote natural riparian vegetation successional patterns.
9 Chutes therefore provide an opportunity to better understand the relationship between
10 physical processes, habitat development, and benefits to pallid sturgeon. It will be
11 important to manage risks and ensure that modification of existing SWH sites generates
12 a net positive effect (i.e., does not reduce the availability of other important habitat
13 types or limit recruitment in the lower Missouri River, either locally or systemically) and
14 does not interfere with the IRC experimental design referenced in section 4.2.6.3.4.
15 Secondary objectives are to contribute to the IRC targets and to ensure that impacts to
16 HCs are minimized.

17 *4.2.6.4.4 Experimental Design*

18 The choice of experimental design used to assess whether existing SWH chute projects
19 can be modified to IRC habitats depends on the quality and quantity of existing data and
20 the anticipated time for chute modifications to yield measurable responses. Some
21 existing chute sites have baseline physical and biological data. Unlike the IRC
22 monitoring proposed above, however, control sites are not available, so the analysis may
23 take the form of a Before-After (BA) design. A key attribute of a BA design is that the
24 impact is immediate. However, habitat changes in response to existing project
25 modifications may take several years. Therefore, comparing the rate and direction of
26 change in the distribution and amounts of suitable food producing and foraging
27 habitats, pre and post construction, within individual chutes may be the most beneficial
28 for determining success at the project scale.

29 An alternative to a simple BA design would be the following BACI or staircase design:

- 30 • Determine the subset of SWH chute projects which could potentially become
31 functional IRC habitats (sites that have no potential for rehabilitation are
32 excluded from the design);
33 • Randomly divide the subset of sites with rehabilitation potential into treatment
34 and control chutes, and immediately begin (or continue) monitoring physical and
35 biological metrics;
36 • Design rehabilitation actions for each chute to be treated;

- 1 • Implement rehabilitation actions in the treatment chutes, either all at once (BACI
2 design) or gradually over time (staircase design);
3 • Monitor both treatment and control chutes for an appropriate length of time to
4 assess trends in physical and biological metrics (at least 6 years after
5 implementation of rehabilitation actions);
6 • Use methods like those described in Wiens and Parker (1995) to compare the
7 trends in physical and biological metrics in treated vs. control sites (the
8 differences between treated and control sites should increase over time in the
9 intended direction if the actions are working); and
10 • If treated sites show significantly greater improvement in physical and biological
11 metrics than the control sites, then design and implement rehabilitation actions
12 in the control sites, so as to increase the benefits to pallid sturgeon.
13 • This schema recognizes that control and treatment chutes will likely vary
14 considerably in their inherent hydrologic and geomorphic characteristics, and
15 this divergence will somewhat lower statistical power.

16 The Nebraska Game and Parks Commission (NGPC) and Missouri Department of
17 Conservation (MDC) have recently proposed an approach for analyzing the availability
18 of habitat in chutes. This method quantifies available age-0 sturgeon habitat within
19 chutes at a specific discharge. Additional information regarding the relationship
20 between flow and habitat availability within chutes at a variety of river stages could be
21 obtained via 2-D modeling. This methodology may prove effective at assessing the
22 evolution of habitat conditions within chutes, and may also allow for comparisons
23 among chutes. This approach could be used to screen existing chutes to identify those
24 that may already be providing significant amounts of IRC habitats, those that require
25 modifications to provide well-functioning IRCs, and chutes that are not likely to provide
26 IRCs. A Chute Assessment and Monitoring Plan will be developed and included as
27 Attachment 2 to Appendix E. This plan will describe the steps necessary to evaluate
28 habitat availability and interception within existing chutes, steps necessary to modify
29 existing chutes to promote IRCs, and a methodology for assessing the progress of
30 modified chutes towards IRCs.

31 4.2.6.4.5 *Metrics*

32 The means objectives by which the USACE will be evaluated in meeting their obligations
33 under the BiOp are based on the net increase in “effective” acreage of IRC habitat (in
34 acre-days/yr) from existing SWH sites. “Effective” acreage will be calculated as
35 described in section 4.2.6.3.5. As described in section 4.2.6.3.5, metrics will be based on
36 measures of depths, velocities, and substrate, including mean and variance, and
37 potentially complemented with metrics of spatial complexity like diversity indices, patch
38 shape, and patch connectivity. Successful rehabilitation of a chute or other habitat unit

1 would be indicated by positive trends in the fraction of the habitat area with suitable
2 habitat characteristics for IRCs, and evidence of desired directions of changes in depths,
3 velocities and substrates according to the site-specific design. Unsuccessful
4 rehabilitation would be indicated by no change (or a decrease) in the fraction of the
5 habitat area with suitable habitat characteristics, and evidence that depths, velocities
6 and/or substrates are not evolving in the desired direction. As for IRCs, increased
7 densities of age-0 fish (as estimated by catch per unit effort) would provide a primary
8 biological performance measure, ideally supplemented by estimates of survival. As
9 discussed in section 4.2.6.3.4, it would be helpful to have an estimate of upstream egg
10 production in that year as a covariate in statistical analyses of before-after, or BACI
11 comparisons, though estimating this covariate will be difficult. Alternatively, a “year
12 effect” could account for year-to-year variations in egg supply.

13 *4.2.6.4.6 Decision Criteria*

14 Decision criteria guide the Technical and Implementation Teams when evaluating
15 monitoring and other information and in developing recommendations for
16 consideration by the agencies. The targets for implementation (Table 42) afford a
17 straight-forward measure of compliance with the means objectives for IRCs at Level 3,
18 computed on an annual basis using 2D hydrodynamic models. Net increases in habitat
19 will be computed on an annual basis. The intention is to permit flexibility to address
20 needs while promoting learning through Level 2 actions and to address programmatic
21 requirements related to pallid sturgeon. Performance relative to targets will be assessed
22 using a running average of annual lift in effective acreage of IRC habitat (described
23 above in section 4.2.6.3.5). Acceptable performance is meeting or exceeding the targets
24 in Table 42 based on a three-year running average for at least 4 of every 5 years (80%
25 success rate).

26 Additional decision criteria for Level 1 and Level 2 studies are listed above in Table 44,
27 and below in Table 53 for Level 2/3 studies. If experimental results in Level 2 studies
28 fail to demonstrate an increase in key metrics relative to control areas and pre-
29 treatment conditions, there are several potential responses depending on syntheses of
30 all lines of evidence: IRC designs and locations may need to be adjusted to be more
31 effective; the hypothesis may need to be refined; the hypothesis should be moved into
32 set of the reserve hypotheses; or the hypothesis should be abandoned. If the
33 experimental results support the hypothesis that channel reconfigurations can provide
34 increased food-producing and foraging functional habitats, and increase pallid sturgeon
35 condition, then the decision would be to move toward Level 3 implementation.

36 Triggers for Moving to Higher Implementation Level: The decision to move from Level 3
37 to full implementation at Level 4 will be based on a validation of a systematic relation

1 between IRCs and increases in growth and survival of age-0 sturgeon that permits
2 modeling of the needed scope and distribution of IRC implementation to meet the
3 fundamental objectives. This judgment should be based on the strength and replicability
4 of relations between abiotic habitat variables describing food and forage habitats, and
5 growth and survival of age-0 sturgeon. In addition, the need for supplemental flow
6 management at Level 3 or 4 would be based on the availability of sound relations
7 between flow conditions, IRC habitat, and growth and survival of age-0 sturgeon.

8 Timeframes: Implementation of IRC habitat at Level 3 will occur no later than two years
9 post-ROD. There is no time limit for the transition to Level 4.

10 *4.2.6.4.7 Level 3 Contingent Actions*

11 Contingency plans for modifying existing SWH projects into IRCs are mainly associated
12 with the secondary objectives (e.g., structure manipulations will not adversely affect
13 navigation); however, adjustments to the targets, habitat criteria, methods, etc. might be
14 required if performance fails to meet expectations. Analyses of performance across
15 multiple water years may reveal flow management strategies that enhance the
16 performance of modified SWH projects.

17 *4.2.6.5 Spawning Habitat*

18 The action of creating spawning habitat relates to Big Question 5: Can channel
19 reconfiguration and spawning substrate construction increase the probability of survival
20 through fertilization, incubation, and hatch?

21 *4.2.6.5.1 Hypotheses*

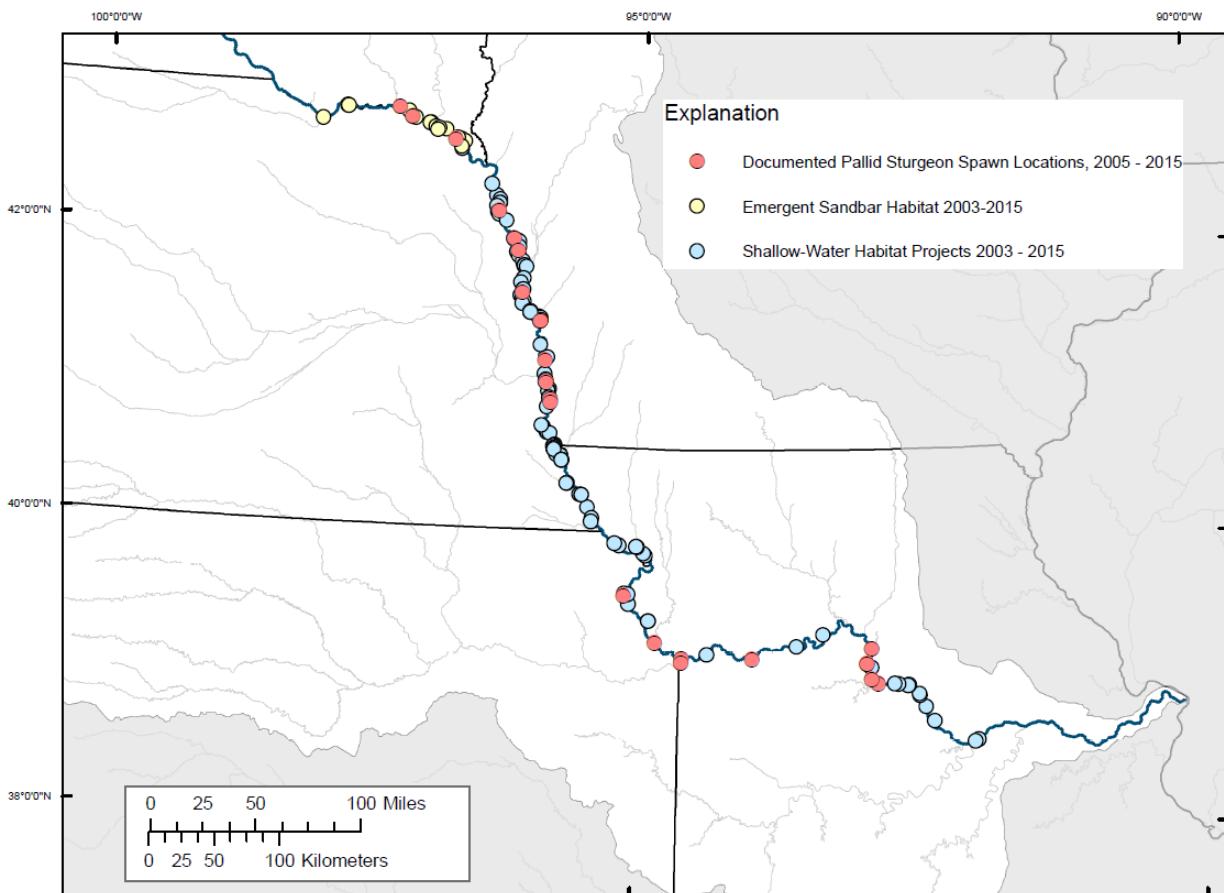

22 The following hypothesis is relevant to this action:

23 H16. Re-engineering of channel morphology in selected reaches will create optimal
24 spawning conditions -- substrate, hydraulics, and geometry -- to increase probability
25 of successful spawning, fertilization, embryo incubation, and free-embryo retention.

26 Delonay et al. (2016) provide a review on what is known and not known about the
27 spawning of pallid sturgeon in the Missouri River, and the subset of sites for which
28 spawning has been rigorously confirmed. Some key points (Robb Jacobson and Aaron
29 Delonay, USGS, pers. comm.) that are helpful for understanding the inherent challenges
30 in testing hypothesis H16 are as follows:

- 1 • Figure 77 shows the distribution of known spawning sites in the lower Missouri
2 River. The spatial distribution of spawning areas in Figure 77 reflects both where
3 females were originally tagged (two groups, one upstream and one downstream)
4 as well as where field observations were able to infer that spawning occurred.
 - 5 • Spawning is most accurately confirmed by intensively tracking the movement of
6 tagged females, and the release of their eggs, usually between the first week of
7 April and the first week of May. Detection of eggs and embryos downstream is
8 further confirmation of spawning, but this has not been done for most of the sites
9 shown in Figure 77. Males tend to aggregate at spawning areas and then wait for
10 females, but it isn't possible to know the distribution or movement patterns of
11 untagged fish (most tagged fish are females raised in a hatchery).
 - 12 • Recent observations indicate that juveniles produced from wild parents are
13 returning to the Nebraska portion of the Missouri River, but this area also has
14 fish in poor condition which could delay spawning (section 4.1.2.4). Net
15 sampling of free embryos, genetic identification and back-calculation of
16 presumed spawning locations based on the advection-dispersion model indicate
17 that fish spawned successfully in 2014 around the Sioux City area above the
18 Platte River.
 - 19 • Tagging permits identification of repeat spawners, which has shown that some
20 females have spawned in the same location in different years, while others have
21 spawned in different locations in different years, sometimes over 100 km apart
22 (Robb Jacobson, USGS, pers. comm.).
 - 23 • Acoustic telemetry is not always sufficiently accurate to identify the exact location
24 of spawning, due to noise interference from boat vessels.
- 25 The EA found that there was theoretical support for hypothesis H16 based on support
26 from sturgeon species and hydrodynamic models, but that data were equivocal as to
27 whether spawning habitat was a limiting factor. It is important to determine whether or
28 not current spawning is successful at existing spawning sites, so as to determine the
29 need for additional spawning habitat, and the attributes of spawning habitat which
30 currently leads to successful spawning. Testing hypothesis H16 will require a nested set
31 of more detailed hypotheses that are structured to be amenable to specific statistical and
32 modeling analyses, discussed further in section 4.2.6.5.6 on Experimental Design.
- 33 The spawning habitat hypothesis (H16) is highly uncertain, with multiple hypotheses
34 influencing potential directions and action. The hypothesis with the highest potential to

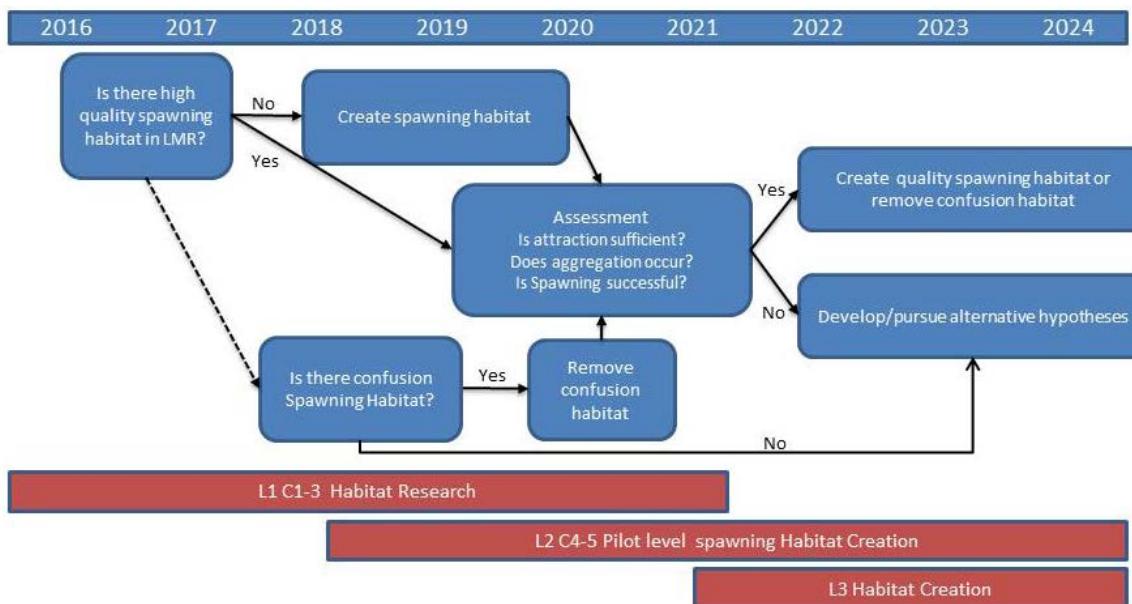

1 provide rapid learning and insight is that high quality spawning habitat is limiting. Pilot
2 projects (at Level 2) to address this hypothesis can be implemented within a few years
3 and could greatly improve our understanding of the relationship between spawning
4 habitat and successful reproduction.

5
6 Figure 77. Distribution of known spawning sites in the lower Missouri River.

7 There are two competing high-level hypotheses regarding spawning habitat concerns:
8 one hypothesis is that additional high-quality spawning habitat is needed, while the
9 opposing hypothesis is that too much poor-quality (i.e. "confusion") spawning habitat
10 exists on the river, dispersing pallid sturgeon among multiple spawning sites. Because
11 the first hypothesis is much easier to test, the AM strategy will focus on that hypothesis
12 first and pursue the confusion habitat hypothesis only if Level 1 or 2 studies reject the
13 first hypothesis or provide added support to the second. Removal of confusion habitat
14 could be very difficult. A decision tree (Figure 78) has been developed to guide the
15 development of decision criteria related to level 1 through 3 spawning habitat activities.
16 An ideal outcome would be that the development of very high quality spawning habitat
17 will attract fish away from low-quality confusion habitat, and that gradual degradation

- 1 of confusion habitat will increase the relative attractiveness of high quality spawning
 2 habitat. If fish are not attracted to the created spawning habitat, this could mean that
 3 either spawning habitat is not limiting, or that the design needs to be adjusted.

4

5 Figure 78. Decision tree for spawning habitat. Source: USFWS and USACOE (2015)

6 4.2.6.5.2 Action Description

7 We presently do not have sufficient understanding to characterize the necessary actions
 8 at Level 3 or determine quantifiable targets for spawning habitat. The focus of Level 1
 9 and 2 will be to reduce the uncertainty regarding spawning habitat characteristics and
 10 needs for successful recruitment.

11 An early emphasis will be to utilize information from the Yellowstone River as the best
 12 natural reference condition to inform the design of Level 2 pilot projects on the Lower
 13 Missouri River, while also continuing to examine the habitat characteristics of spawning
 14 sites on the Lower Missouri. Pilot projects on the Lower Missouri will be monitored for
 15 effectiveness based on metrics ranging from observed aggregation to the number of free
 16 embryos in the water column (described below in section 4.2.6.5.5 on metrics). Level 3
 17 targets for spawning habitat may be beyond the 15 year timeline under the planning
 18 process, depending on the rate of learning from Level 2 activities. If hypothesis H16 is
 19 correct (spawning habitat is limiting), costs and impacts on other uses should be
 20 relatively low, and construction relatively easy. In contrast, should the confusion
 21 hypothesis be true, the costs and potential impacts on other uses are likely to be much
 22 greater.

C5 Manipulative field experiment for spawning habitat																	
Level 3																	
If successful and appropriate, expand spawning habitat																	

Figure 79. Proposed sequencing of actions and studies for spawning habitat, revised from USFWS and USACOE (2015) to reflect current USFWS priorities and timelines.

4.2.6.5.3 Objectives

The objectives of Level 1 studies of spawning habitat are to:

- Determine the characteristics of ideal spawning habitat for pallid sturgeon, based on observations of successful spawning sites on the Yellowstone River (BQ5/L1/C1 in Table 44);
- Assess the habitat characteristics of historical spawning sites on the Lower Missouri River (BQ5/L1/C2 in Table 44); and
- Use mesocosms to experimentally determine how spawning varies with depth, velocity, substrate, hydraulic variables and water quality (BQ5/L1/C3 in Table 44).

Level 2 studies have the following objectives:

- Apply advection dispersion models, population models and engineering studies to determine how to create and sustain the ideal hydraulic and substrate conditions determined from Level 1 studies, and to evaluate appropriate locations (river segments) for creating spawning habitat based on both past utilization and channel / substrate characteristics (BQ5/L1/C4 in Table 44).
- Create at least 1high quality spawning habitat site (Table 42) , and monitor the effectiveness of this action in terms of the *relative use* of this site compared to control areas, and the *relative spawning success*, as determined by hatch rate, catch per unit effort of free embryos and other indicators (BQ5/L1/C5 in Table 44).

Though multiple high quality spawning habitat sites would have benefits from the perspective of experimental design (i.e., a replicated treatment), initially developing just one high quality spawning site appears to be preferable from a biological perspective (i.e., more likely to concentrate males and females at one location and time, reduced risk of hybridization with shovelnose sturgeon, greater ability to target flow manipulations if they are implemented in the future – discussed in section 4.2.6.6). The

1 tradeoffs between a single site versus multiple sites are discussed further under section
2 4.2.6.5.6 , Experimental Design.

3 *4.2.6.5.4 Expected Benefits*

4 If Level 1 and Level 2 studies fulfill their objectives, and Level 2 pilot / proof-of-concept
5 projects show improved spawning success over control areas, it will allow the
6 development of Level 3 designs for a larger scale spawning site (or possibly two
7 spawning sites if it appears that pallid sturgeon naturally aggregate in different areas). If
8 the proof-of-concept shows benefits at a site scale, then scaling up should increase both
9 spawning success and the abundance of pallid sturgeon in the Lower Missouri River.

10 *4.2.6.5.5 Metrics*

11 Many of the metrics associated with the creation of spawning habitat are identical to
12 those for the Intake Dam (described in section 4.2.5.2.5). Metrics for spawning habitat
13 creation can be organized around a series of questions:

14 **Has suitable spawning habitat been created and maintained?** Habitat will be
15 characterized in terms of suitable depth, velocity, substrate, and derivative hydraulic
16 variables (based on studies of Yellowstone spawning), with covariates relating to water
17 quality and fish behaviors. Pallid sturgeon minimize their energy expenditure by
18 migrating up inside bends, and then traverse across to outside bends when they're ready
19 to spawn. Spawning habitat sites will create cross-over points at appropriate outside
20 bends, using a sill across the river to minimize the amount of sand carried over it, while
21 at the same time ensuring that navigation is not affected. Physical monitoring of these
22 sites will involve ensuring that the desired habitat characteristics are being naturally
23 maintained through natural or managed flow releases. One measure of site quality is to
24 compare measured hydraulic variables with the rate at which unfertilized eggs fall down
25 through the water column to evaluate whether eggs are likely to be deposited in the
26 manipulated habitats. In the Yellowstone River, spawning females selected small
27 patches of gravel between dynamically moving sand dunes, whereas the expectation
28 based on past observations was to see spawning on hard substrates. This variability in
29 habitat selection suggests that providing a range of depths, velocities and substrates
30 within a large site would help to determine habitat preferences at a fine spatial scale.
31 Level 1 mesocosm experiments (BQ5/L1/C3 in Table 44) will also be helpful to
32 determine preferences for spawning habitat.

33 **Are created spawning habitats preferred over other areas?** With a fixed
34 telemetry network it should be possible to determine the number of times each
35 reproductively ready female encounters the created spawning habitat site, and how

1 often she encounters other potential spawning sites (i.e., outside bends of rivers).
2 Relative preference can then be calculated based on the ratio of documented spawning
3 events to encounter events, for both created and potential spawning sites. The statistical
4 power to detect this relative preference will be proportional to the number of tagged
5 fish in reproductive condition. To detect differences in habitat selection between a
6 created spawning site(s) and control areas, one would ideally have at least 10 to 20
7 spawning females in reproductive condition at each location, as well as an
8 approximately equal number of males (Aaron Delonay, USGS, pers. comm.). With fish
9 spawning only every 3 years, and roughly two groups of 40 tagged fish in the upper and
10 lower part of the Lower Missouri (mostly females), attaining such sample sizes is
11 unlikely to occur in most years, particularly if many fish remain in poor condition and
12 delay reproduction. One way in which to increase sample sizes would be to precondition
13 a group of 30-40 adult fish to a reproductive state in a hatchery, and then release them
14 downstream of both treated and control sites with fixed telemetry detectors. The
15 feasibility of such an experiment depends upon the outcome of the Basin-wide Stocking
16 and Augmentation Plan for pallid sturgeon.

17 Other metrics relevant to this question are measures of fish aggregation and spawning
18 behaviors (for example, optimum male: female ratios in spawning aggregations), and
19 the degree of attraction/specificity of adults to different spawning substrates.

20 **Does successful spawning occur in the created spawning habitats?** This
21 question is very similar to Q3 discussed in Table 46 for Intake (Does successful
22 spawning and aggregation occur?), and Q3 in Table 48 for spawning cue flows (Do
23 upstream movements and spawning aggregations lead to documented successful
24 spawning?), and would use similar metrics. Multi-receiver, 3D telemetry and DIDSON
25 (Dual Frequency Identification Sonar) video can be used to evaluate behaviors of
26 reproductive adults on the spawning patches to identify spawning aggregations and egg-
27 release events. The ultimate metric for spawning habitat is hatch rate as a function of
28 habitat availability. Deploying ichthyoplankton nets downstream of sites with apparent
29 spawning is used to capture eggs and embryos to confirm that spawning has occurred.
30 Females can also be recaptured to determine if they have released their eggs. Repeat
31 high-resolution multi-beam maps of the spawning patches during incubation will
32 indicate whether the substrate is subject to burial or erosion, which is likely to result in
33 zero hatch. Monitoring of age-0 fish downstream of spawning habitats will be
34 important; a redesigned PSPAP (Appendix D), including increased numbers of
35 genetically tested age-0 sturgeon, will help to improve evaluation of recruitment.

36 **Is recruitment successful and sufficient to meet population targets?** This
37 question depends on the outcome of not only spawning, but also survival of free

1 embryos and feeding larvae over the first year of life. The primary metric is catch rates
2 of age 0 and age 1 pallid sturgeon; secondary metrics include model-based estimates of
3 abundance of age 0 and age 1 pallid sturgeon, and the survival of hatchery and naturally
4 reproducing fish to age 1.

5 *4.2.6.5.6 Experimental Design*

6
7 The experimental design of L2 spawning habitat actions needs to accomplish three
8 things: 1) maximize the effectiveness of newly created spawning habitat; 2) create
9 contrasts over space and time to evaluate the effectiveness of this habitat (test
10 hypothesis H16); and 3) avoid confounding from other potential L2 and L3 actions.

11 **Potential Locations.** Spawning habitat would ideally be placed in locations which
12 maximize aggregation of males and females, spawning success, and the survival of
13 spawners' progeny (i.e., embryos, exogenously feeding embryos and larvae). The EA
14 suggested that sites should be located where they would be encountered by reproductive
15 pallid sturgeon at or near the upstream apex of their reproductive migration (Jacobson
16 et al., 2016a). Level 1 studies (especially observations of spawning migrations and
17 locations) and Level 2 engineering and modeling studies (Table 44, Big Question 5) will
18 help to determine the best locations.

19 Figure 74 shows potential locations for newly created or enhanced spawning habitat
20 between Sioux City and Decatur, and between Decatur and Omaha. The area between
21 Sioux City and Decatur provides a convergence of four attributes: near the upstream
22 apex of reproductive migrations; close enough to Gavins Point Dam to ensure that flow
23 pulses maintain spawning habitat quality; far enough downstream from Gavins Point
24 Dam to allow for the recovery of some turbidity in the river (necessary to reduce
25 predation on embryos); and far enough upstream to allow sufficient drift distances for
26 embryos to mature into feeding stages and utilize IRC habitat much farther downstream
27 (also in Figure 74). Locating spawning habitat downstream, say near Booneville,
28 Missouri, would provide free embryos that would drift into the Middle Mississippi
29 River. While such fish might still potentially return to the Missouri River, they would
30 not be sufficiently mature to utilize IRC habitats in the Missouri River and therefore
31 might have lower survival. Other potential locations for creating spawning habitat
32 include the unchannelized 59-mile reach below Gavins Point.

33 As stated above, it would be preferable to initially implement only one spawning site. If
34 however, evidence were to indicate that aggregations were occurring naturally in more
35 than one area after creation of the first spawning site, and/or it were possible to use
36 preconditioned hatchery fish for a spawning site selection experiment, then the area

1 between Decatur and Omaha might be another possible location for a future spawning
2 site. A site between Decatur and Omaha would avoid confounding the effectiveness
3 monitoring of two level L2 actions: spawning habitat creation and spawning cue flows. A
4 spawning cue flow (if it were implemented after year 9 from Gavins Point – see section
5 4.2.6.6) would dissipate downstream, allowing for the utilization of spatial contrasts
6 within the years that such flows occur. If spawning habitat sites were only available
7 between Sioux City and Decatur, and this portion of the river were also subject to a
8 strong signal from an L2 spawning cue flow, then it would be difficult to determine
9 whether a concentration of spawners at these sites were due to the spawning cue flow,
10 the spawning habitat, or both. Providing an additional spawning habitat site further
11 downstream between Decatur and Omaha (an area with a weaker signal from a Level 2
12 spawning cue flow) would help to reduce the potential confounding of the two
13 treatments (i.e., spawning cue flows and spawning habitat creation).

14 In their review of Version 3 of the AMP, the ISAP (2015) made the following comment,
15 which suggests it would also be worth considering creating spawning habitat in the
16 upper reaches of the Lower Missouri River:

17 A potential justification for focusing on reproductive success in the upper
18 reaches of the lower Missouri River is that embryos produced farther
19 upriver would be more likely to remain in the Missouri River rather than
20 being transported to the middle Mississippi River, depending on flow
21 conditions. And, the role of the Mississippi River in providing rearing
22 capacity for pallid sturgeon that might later migrate into the lower
23 Missouri River to mature and reproduce remains unclear. If that capacity
24 is high, then suitable spawning habitat in most locations on the lower
25 Missouri River could provide valuable contribution to pallid sturgeon
26 recovery. [pg. 19]

27 Development of spawning sites at Level 2 would logically proceed with a proof-of-
28 concept at one location, and necessary adjustments to the design until success is
29 achieved or the hypothesis is rejected. If success is achieved, and the first site shows
30 evidence of over-crowding, then it would be worth considering expanding the first site
31 prior to building additional sites, so as to maintain aggregation. ,

32 **Are created spawning habitats preferred over other areas?** The experimental
33 design would involve the use of a stationary telemetry network to determine the number
34 of *actual spawning events* (i.e., selecting a site for spawning) and the number of
35 *encounters with potential spawning sites*, for both the created spawning habitat and *n*
36 control areas for telemetered fish (every outside bend encountered by a spawning
37 female is a potential spawning site and therefore a control area). The prediction to be
38 tested (consistent with hypothesis H16) is that the ratio of actual spawning events to

1 encounters with potential spawning sites will be significantly higher for the newly
2 created spawning habitat than for the control sites.

3 **Does successful spawning occur in the created spawning habitats?** The
4 metrics described above in section 4.2.6.5.5 would be measured at the newly-created
5 spawning site and 3 control sites that were selected for spawning. The prediction to be
6 tested (consistent with hypothesis H16) is that spawning success (assessed by multiple
7 metrics) will be higher at the newly created spawning sites than at the control sites.

8 **Are newly created spawning sites beneficial for the population?** By definition,
9 actions at Level 2 are at an insufficient scale to have an *actual* effect on the population
10 (see Table 39), and therefore the effects of Level 2 spawning habitat creation would not
11 be expected to be detected in population monitoring. However, the potential population
12 benefits of this action can be inferred through the use of the collaborative population
13 model. For example, if the probability of site selection and successful reproduction was
14 5 to 10 times higher at spawning sites than at control sites, one could model the
15 potential population benefit of such an effect.

16 **4.2.6.5.7 Decision Criteria**

17 Decision criteria guide the Technical and Implementation Teams when evaluating
18 monitoring and other information and in developing recommendations for
19 consideration by the agencies. The relevant decision for the Level 2 studies associated
20 with hypothesis H16 would be whether to move forward into full implementation,
21 change the experimental patch design, or abandon the spawning habitat quality
22 hypothesis and pursue the confusion habitat hypothesis. Robust statistical results
23 cannot be expected for the preferred metric (hatch rate) because of the difficulties in
24 enumerating this under field conditions. However, the results of other metrics
25 described above should contribute to a lines-of-evidence decision of whether the
26 spawning patches are functioning as intended.

27 **Criteria for Accepting or Rejecting Hypotheses:** Lines of evidence discussed above for
28 each question.

29 **Triggers for Moving to Higher Implementation Level:** Fish use created spawning
30 habitats in multiple years at a rate significantly greater than control sites; hatching
31 success is greater at created spawning sites than at control sites; the simulated benefits
32 of high quality spawning habitat (based on empirical measurements) suggest that
33 scaling up the action to Level 3 or 4 would have a significant benefit to the pallid
34 sturgeon population.

1 Timelines: No specific timeline for these hypotheses has been established, though the
2 timelines in the above figures provide a sense of the expected outlay of effort and the
3 sequencing/dependencies of certain activities.

4 4.2.6.5.8 *Level 3 Contingent Actions*

5 Information provided through field experimentation will indicate whether channel
6 geometries and/or substrate should be altered to improve performance of spawning
7 patches, and whether additional locations would contribute to spawning success and
8 population growth. Rejection of the “quality habitat” hypothesis would result in pursuit
9 of the alternative “confusion habitat” hypothesis, though the daunting nature of that
10 undertaking has prevented an outlay of the necessary actions to date.

11 4.2.6.6 *Spawning Cue Flows*

12 The action of creating spawning cue flows relates to Big Question 1 for the Lower
13 Missouri River: Can spring pulsed flows synchronize reproductive fish, increase chances
14 of reproduction and recruitment? As described in Table 42, the MRRMP-EIS assumes
15 that Level 1 actions would occur after a ROD for up to 9 years prior to the possible
16 implementation of spawning cue flows at Level 3. At the end of this 9-year period, the
17 Technical Team would apply the decision criteria and evidentiary framework shown in
18 Table 48 to determine if it were appropriate to implement spawning cue flows at either
19 Level 2 (test flows to create more contrast, test hypothesis H11 (listed below) and create
20 possible biological benefits) or (if the Level 2 test proves to be successful) at Level 3
21 (flows to generate biological benefits).

22 What constitutes a *sufficient contrast of flows* would be determined by objective
23 analysis of the data by the Technical Team at the end of the 9-year period, and peer
24 review of these conclusions by the ISAP (and likely peer review for journal publications).
25 *Successful spawning* is confirmed by: colocation of females and males; multi-receiver,
26 3D telemetry and acoustic video to confirm egg release events; downstream capture of
27 viable eggs and embryos; and recapture of spawned females that have released eggs.
28 *Unsuccessful spawning* is confirmation of an interruption of any of the steps that lead
29 to successful spawning (i.e., movement, aggregation, egg release, embryo creation).

30

31

32

Table 48 Evidentiary Framework for Flow Observations. This decision aid is intended to determine if sufficient spawning cue flow events occur during the first nine years of implementation post ROD, and to determine if an explicitly managed spawning cue flow should be implemented after the ninth year to test flow hypotheses.

Question	Potential Metrics and Lines of Evidence Based on Observations over 9 years		
	No [👎👎👎 or 🤢]	Inconclusive [🤷]	Yes [👍👍 or 🤝🤝]
Q1. Are there attributes of river flow that are strongly correlated with upstream movement of male and female pallid sturgeon of reproductive age?	Sufficient contrast of flows has occurred over first 9 years to answer this question, and movements of pallid sturgeon have been well monitored, but no significant correlations are apparent between flow and movement. Flows aren't associated with movement.	Insufficient contrast of flows has occurred over first 9 years to be able to rigorously answer this question. Effects of flows unclear.	Sufficient contrast of flows has occurred over first 9 years to answer this question, movements of pallid sturgeon have been well monitored, and significant correlations are apparent between flow and movement, at flow magnitudes that could be released by managers. Flows are associated with movement.
Q2. Are there attributes of river flow that are strongly correlated with immediately subsequent spawning aggregations of telemetered male and female pallid sturgeon of reproductive age?	Wide contrast of flows has occurred over first 9 years (below and above potential spawning flows) and movements of telemetered pallid sturgeon have been well monitored, but no significant correlations are apparent between flow and spawning aggregations. Flows aren't associated with aggregation.	Insufficient contrast of flows has occurred over first 9 years to be able to rigorously answer this question. Effects of flows unclear.	Wide contrast of flows has occurred over first 9 years (below and above potential spawning flows), movements of telemetered pallid sturgeon have been well monitored, and significant correlations are apparent between flow and spawning aggregations, at flow magnitudes that could be released by managers. Flows are associated with aggregation.
Q3. If the answers to Q1 and Q2 were "yes", do upstream movements and spawning aggregations lead to documented successful spawning?	n.a. [Answers to Q1 and Q2 were "No", so Q3 does not apply. If successful spawning did occur, it was not due to flow-triggered movement and aggregation]	n.a. [Answers to Q1 and Q2 were "Inconclusive", so Q3 does not apply.]	Successful spawning observed at spawning sites (gravid females released eggs in the presence of males), following flow-associated upstream movement and spawning aggregations. Strong evidence that flows support spawning.
Q4. If successful spawning occurs (and answers to Q1, Q2 and Q3 are "yes"), are viable embryos found downstream of the spawning site?	n.a. [Answers to Q1 and Q2 was "No", so Q4 does not apply. If successful spawning did occur, it was not due to flow-associated movement and aggregation]	n.a. [Answers to Q1 and Q2 were "Inconclusive", so Q4 does not apply.]	Viable embryos found downstream of successful spawning events that are genetically related to the males and females observed to be spawning. Very strong evidence that flows support spawning.
Q5. Do successful spawning events occur sufficiently frequently under current water management rules to prevent jeopardy and support recovery?	No. Successful spawning does not occur frequently enough under current water management rules to prevent jeopardy and support recovery.	Inconclusive (e.g., not enough tagged fish to estimate total spawning success)	Yes. Successful spawning occurs frequently enough under current water management rules to prevent jeopardy and support recovery.
Conclusions regarding need for spawning flows after Year 9	<u>No to Q1-Q2:</u> Do not implement spawning flows at Level 2. <u>Inconclusive to Q1-Q2:</u> Implement spawning flows on a trial basis (Level 2) to get enough contrast and answer Q1-Q4. <u>Yes to Q1-Q2 and No to Q5:</u> Possibly implement spawning flows on a trial basis (Level 2), and do research to understand what else is limiting spawning success (e.g., substrate, predation). <u>Yes to Q1-Q2 and Yes to Q5:</u> Rely on natural flows from tributaries to trigger movement and aggregation, and do research to understand what else is limiting spawning success. <u>Yes to Q1-Q4, No to Q5:</u> Possibly implement spawning flows on a trial basis (Level 2), and if successful, continue to do so once every 3 years (Level 3). Continue to monitor movement, aggregation, spawning. <u>Yes to Q1-Q5:</u> Rely on natural flows from tributaries to trigger movement, aggregation, and successful spawning. Continue to monitor movement, aggregation, spawning.		

1 4.2.6.6.1 *Hypotheses*

2 The following hypothesis is relevant to this action:

- 3 • H11. Naturalization of the flow regime at Gavins Point Dam will improve flow cues in
4 spring for aggregation and spawning of reproductive adults, increasing reproductive
5 success.

6 The EA (Jacobson et al., 2016a) found that while there was theoretical support for this
7 hypothesis based on inferences from other sturgeon species, that there were inadequate
8 data to model and forecast consequences of this action (Table 38). Earlier, the
9 Independent Science Advisory Panel (ISAP 2011; pg. 1-2) concluded that {italics added}:

10 Pallid sturgeon have spawned in the lower Missouri River in all years for
11 which data are available, with and without managed spring pulses. Based
12 on that information, the ISAP concludes that the spring pulse
13 management action, *as currently designed*, is unnecessary to serve as a
14 cue for spawning in pallid sturgeon.

15 It therefore is important to gain a better understanding of the mechanisms and factors
16 which stimulate spawning in pallid sturgeon.

17 4.2.6.6.2 *Action Description*

18 A series of Level 1 and Level 2 studies (described in Table 44 and Appendix C) would be
19 completed prior to implementation of any Level 3 spawning cue flow at Gavins Point.
20 These studies include:

- 21 • Designing a passive telemetry network, and associate power analyses to determine
22 how large of a change in spawning would be detectable (BQ1/L1/C1a)
23 • Statistical power analysis and biological modeling of potential population benefits
24 (BQ1/L1/C1b); and
25 • Continuation of opportunistic tracking of reproductive behaviors to determine the
26 degree of association of reproductive behaviors and successful spawning with
27 monitored hydrologic characteristics (BQ1/L1/C2).

28
29 Opportunistic tracking of pallid sturgeon (BQ1/L1/C2) would involve the following
30 components, in **both** the Upper and Lower Missouri River, as both areas can help to
31 test hypotheses related to spawning cue flows:
32

- 1 • opportunistic monitoring of water discharge, pallid sturgeon movement, and
- 2 pallid sturgeon location data
- 3 • flows, temperature and turbidity measured continuously at multiple locations
- 4 downriver from Fort Peck and Gavins Point Dams, and on the lower Yellowstone
- 5 River
- 6 • tracking of pallid sturgeon in reproductive condition via telemetry to determine
- 7 movement patterns, documenting reproductive behavior (aggregation,
- 8 synchronization, spawning)
- 9 • monitoring spawning success by site observations and measuring the production
- 10 of free embryos (see section 4.2.6.5.5 describing metrics for assessing the
- 11 effectiveness of spawning habitat creation)
- 12 • evaluation of the statistical relationships of flow-regime components (e.g., mean
- 13 discharge, peak discharge, change in discharge), and covariates (turbidity and
- 14 temperature) to pallid sturgeon behavior
- 15 • for the Lower Missouri River, examination of the influence of flows at both
- 16 created spawning habitat and at reference locations, since spawning habitat
- 17 creation could also influence spawning behavior.

18 As is clear from the evidentiary framework in Table 48, a range of opportunistic flows
19 (low to high) is needed to bracket ecologically ineffective and effective flows. Variation
20 in flows between the Upper Missouri River and the Yellowstone River will provide a
21 strong experimental contrast in the Upper Missouri. Variation in flows between Sioux
22 City to Omaha and Kansas City to St. Charles will provide strong experimental contrast
23 in the Lower Missouri. However, the number of telemetered fish may limit the
24 inferential power of studies undertaken in the Lower Missouri.

25 A description of a spring pulse sufficient to define a Level 3 implementation, developed
26 in USFWS and USACE (2015) is presented in Table 49. If it were decided after year 9
27 (post-ROD) to proceed with a Level 2 test of spawning cue flows, the flow attributes in
28 Table 49 would likely be modified based on what has been learned during years 1-9,
29 including the requirements for pallid sturgeon, the benefits of this action, the potential
30 effects on tern and plover nesting success, and the distribution and magnitude of
31 effects on human considerations. The design of a Level 2 test of spawning cue flows
32 would also require further sensitivity analyses of the effects on human considerations,
33 sturgeon and bird populations.

34 A maximum frequency of 1 in 3 years was agreed upon by the USFWS and USACE
35 (2015) as an estimate for the purposes of assessing effects on human considerations
36 during the EIS. Decisions on the required frequency of spawning cue flows would
37 depend on the outcomes of the first test of Level 3 flows, together with other evidence

1 from opportunistic monitoring, and simulations from the collaborative sturgeon
2 population model. Level 3 spawning cue flows are currently conceived as bi-modal pulse
3 flows from Gavins Point Dam (Table 49). Options for increasing the variability in the
4 overall pulse height should be explored to more closely mimic the variability that
5 occurred naturally as a means of precluding impacts on sandbar nesting birds.

6 Table 49. Proposed characteristics of Level 3 spawning cue flows.

The first pulse from Gavins Point would conform to the following guidelines:

- Rise begins on first day after flow to target navigation flows are achieved.
- Peak release from Gavins Point is equal to double the flow to target level release the first day of navigation flow to target levels are achieved from Gavins Point
- Increase to peak by 2,200 cfs per day
- Maintain peak for 2 days
- Reduce pulse by 1,700 cfs/day until releases are back to base flow to target levels

The second pulse is cued by water temperature (**16-18 degrees**) at Sioux City Iowa as follows.

- Checks to implement release increases
 - > 40.0 MAF in System Storage on March 15 storage check
 - Steady release has been set and implemented for 3 days
- Releases from Gavins Point
 - Rise begins on May 18 or later based upon water temperature and implementation of steady release for at least 3 days
 - Increase to peak by 2,200 cfs per day
 - Peak release from Gavins Point is equal to twice the steady release from Gavins Point
 - Maintain peak for 2 days
 - Reduce pulse by 1,900 cfs per day until the steady release flows are reached
- Flood targets will be the full service flood targets increased by the steady release level
 - If the steady release is 31 kcfs and the full service flood targets are 41 kcfs, 47 kcfs, and 71 kcfs at Omaha, Nebraska City, and Kansas City, respectively, the new flood targets will be 72 kcfs at Omaha (31 + 41), 78 kcfs at Nebraska City (31 + 47), and 102 kcfs at Kansas City (31 + 71).

Figure 80. Preliminary sequencing of actions and studies for spawning flow cues, revised from USFWS and USACE (2015) to reflect the preferred alternative and current USFWS priorities and timelines. In the preferred alternative for the MRRMP-EIS, a test Level 2 flow would only occur after 9 years of post-ROD monitoring, and if supported by the evidentiary framework in Table 48.

4.2.6.6.3 Objectives

Spawning cue flows are intended to elicit a movement response in gravid pallid sturgeon that results in an aggregation of reproductively ready pallid sturgeon, and thereby improve both reproductive success and recruitment to the population.

4.2.6.6.4 Expected Benefits

If the evidentiary framework in Table 48 leads to the conclusion that Level 2 spawning cue flows are warranted, the expected benefits will be a more definitive test of the effectiveness of this action. If the Level 2 experiment in turn shows biological benefits (i.e., movement, aggregation and successful spawning), then Level 3 flows are likely to increase reproductive success, increasing the probability of survival and recovery. Implementation of such flows would need to be done in a manner which had acceptable impacts on both birds and human considerations. The remainder of this section assumes that the evidentiary framework leads to the conclusion that Level 2 spawning cue flows would be implemented after year 9, and that Level 3 spawning cue flows would follow.

4.2.6.6.5 Metrics

Many of the metrics associated with spawning cue flows are identical to those for the Intake Dam (described in section 4.2.5.2.5) and for the creation of spawning habitat (described in section 4.2.6.5.5). Success metrics for spawning cues are generally related to fish behavior (reproductive migrations, aggregation and successful spawning with monitored experimental flow pulses) and successful reproduction (hatch rate, capture of free embryos, etc. as discussed above for spawning habitats in section 4.2.6.5). Practical assessment of spawning success in the near-term is extremely difficult, so it will be necessary to rely upon behavioral monitoring. Intensive telemetry tracking data of reproductive adults (males and females) will be evaluated against time series of

1 hydrologic characteristics and will be analyzed for the degree of association.
2 Reproductive success or failure is inferred by recapturing reproductive fish soon after
3 expected spawning events to determine if they have released gametes, as well as
4 monitoring the abundance of age-0 fish (critical to a determination of recruitment
5 success). If required based on the evidentiary framework in Table 48, monitoring of one
6 test flow at Level 2 would provide important information to supplement the inferences
7 gained from opportunistic monitoring at Level 1, but it would only be one instance of the
8 experiment. Monitoring of a series of Level 3 flow releases over several years would
9 provide more extensive information, from which one could hopefully establish a
10 functional relationship between flow-pulses and the probability of producing viable
11 larvae. The value of repeating flow releases would depend on the outcome of a one-time
12 test.

13 Another important component of monitoring (for both natural and managed flows) will
14 be determining how the exposure of fish to changing flows and temperatures varies as
15 one moves downstream of Gavins Point. The shape of the hydrograph created by natural
16 or managed flow releases from Gavins Point will be altered as other tributaries enter the
17 Missouri River, and the signal from Gavins Point will be decreased. If pallid sturgeon
18 are affected by a spawning cue flow from Gavins Point, this will likely occur upstream of
19 the Platte River. Sudden decreases in temperature due to changing weather patterns can
20 disrupt pallid sturgeon reproductive migrations which apparently were associated with
21 flow pulses (Robb Jacobson and Aaron Delonay, USGS, pers. comm.).

22 **4.2.6.6 Experimental Design**

23 In a similar manner to the creation of spawning habitats, the experimental design of L2
24 spawning cue flows needs to accomplish three things: 1) maximize the effectiveness of
25 spawning cue flows, building on the learning from Level 1 studies; 2) create contrasts
26 over space and time to evaluate the effectiveness of this action and test hypothesis H11;
27 and 3) avoid confounding from other potential L2 and L3 actions (i.e., spawning habitat
28 creation, discussed above in section 4.2.6.5.6). If hypothesis H11 is true, it would lead to
29 the prediction that in years and locations with a spawning cue flow, more adult pallid
30 sturgeon would migrate to and then aggregate at all potential spawning habitats (newly
31 constructed, older constructed, and natural spawning habitat locations), as compared to
32 years and locations without a spawning cue flow. Testing hypothesis H11 involves both
33 temporal and spatial contrasts.

34 **Temporal Contrasts.** Ideally, contrasts would involve comparing the aggregation of
35 pallid sturgeon in *treatment* years where managers implemented a spawning cue flow
36 with other *control* years in which managers did not implement the spawning cue action.
37 If only one managed flow is implemented, then responses in that year would be

1 compared to other control years with generally similar levels of runoff but without a
2 'suitable flow peak' in April or May. If a Level 2 managed flow were to be implemented
3 (say in years 10 or 11 after the ROD) and it were subsequently decided to implement
4 Level 3 spawning flows every third year, it would then take 15 years to have 5 treatment
5 years. A major challenge with this comparison is that the treatment years are likely to
6 occur in years with lots of reservoir storage and low natural flows (to avoid flood
7 impacts), while non-treatment years could have either low, medium or high natural
8 flows. High natural flows might act as a natural stimulus for spawning aggregations, so
9 these years would be more like a *natural treatment* year than a true control year, and
10 spring flow pulses commonly occur naturally. In summary, only a subset of non-
11 treatment years would be appropriate control years, and criteria for selecting control
12 years will need to be established before Level 2 and Level 3 flow experiments are
13 conducted. Comparisons across years could be confounded by changes in the number of
14 reproductive fish (e.g., decrease of old natural fish; recruitment to spawning of initial
15 hatchery stocks), or sudden changes in temperatures (which also affect spawning). The
16 number of reproductive fish, and river temperatures should therefore be used as
17 covariates in the analysis.

18 It will be important to simulate this experiment using the collaborative population
19 model linked to the river hydrologic model, so as to determine what magnitude of
20 differences in reproductive behavior are likely to be detectable at reliable levels of
21 statistical power with different numbers of tagged fish. For example, tracking 25 tagged
22 adults with a stationary telemetry network might be sufficient to reliably detect the
23 difference between a 1.0 probability of spawning in treatment years and a 0.0
24 probability of spawning in control years, whereas 50 tagged adults might be required to
25 reliably detect a less extreme (and perhaps more likely) magnitude of effect (e.g., 0.6
26 probability of spawning in treatment years and 0.3 probability in control years)¹. It
27 might be possible to increase the number of tagged fish by tagging reproductive
28 hatchery fish that are not being used in the hatchery to avoid inbreeding effects. It
29 would be informative to compare the migration, aggregation and reproduction of such
30 tagged and preconditioned fish in years with and without spawning cue flows, thereby
31 testing the effectiveness of both spawning cue flows and created spawning habitat.

32 **Spatial Controls.** In a year with a managed spawning cue flow, it should be possible to
33 compare spawning behavior at locations upstream of the Platte River confluence where
34 the spawning cue signal is stronger, versus locations downstream of the confluence
35 where the signal gets diluted. This requires careful design of the managed spawning cue
36 flow so that there is a clear signal. Purely from the perspective of a strong experimental

¹ These are just hypothetical examples, not actual calculations of statistical power.

1 design that separates confounding factors, it would be ideal to have spawning habitats in
2 both upstream and downstream locations, so that the effects of spawning habitats could
3 be disentangled from the effects of spawning flows. However, from the perspective of
4 improving spawning aggregation, it will be preferable to only construct one spawning
5 habitat, so as to not distribute spawners across multiple sites.

6 *4.2.6.6.7 Decision Criteria*

7 Decision criteria guide the Technical and Implementation Teams when evaluating
8 monitoring and other information and in developing recommendations for
9 consideration by the agencies. Decision criteria for implementing a spawning cue flow
10 after the first 9 years post-ROD are described in the evidentiary framework (Table 48).
11 If a spawning cue flow were implemented after year 9, the significant experimental
12 control that could be exerted over this action (above the confluence of the Platte and
13 Missouri Rivers) will enhance the ability to detect and quantify reproductive behavioral
14 changes related to flow pulses. However, the flow pulses will still take place within a
15 system where many sources of variability are not controlled, such as weather systems
16 that can abruptly change water temperature or discharge in the mainstem or tributaries.
17 As discussed above in section 4.2.6.6.6 (Experimental Design), there are several
18 confounding factors which will make it challenging to separate the flow pulse signal
19 from other noise in the system created by spatial and temporal variability in flows. It is
20 therefore unlikely that these experiments will result in a statistically rigorous result.
21 Instead, a decision to accept the value of manipulated flow pulses in increasing pallid
22 sturgeon reproductive success, or to reject it, will probably be based on judgement of
23 multiple lines of evidence.

24 Timelines: The time to implementation at Level 3 and sequencing of this action should
25 be considered in light of other actions. For example, before managers run a flow pulse,
26 they should be assured that functional spawning habitat is available, and that a
27 sufficient number of tagged fish in reproductive condition are present in the river to
28 assess aggregation and spawning. This could mean that additional engineered spawning
29 habitat needs to be in place (see section 4.2.6.5), but presently available spawning sites
30 may suffice to address behavioral metrics. A nine-year time limit for implementation at
31 Level 2 was agreed upon by the USFWS and the USACE to allow for habitat and
32 propagation efforts to enhance the potential success of spawning cue flows (see Section
33 4.2.1.3). Information derived from passive monitoring of natural flow events could yield
34 a number of different outcomes relative to hypothesis H11 (Table 48), and lead to the
35 conclusion that a spawning cue flow would not be required. The degree of natural
36 variability in flows over the first nine years will be a primary determinant of the ability
37 to test hypothesis 11.

1 Triggers for Moving to Levels 3 or 4: The trigger for moving to Level 3 implementation
2 would be convincing evidence of upstream movement, aggregation and successful
3 spawning in response to one or more instances of Level 2 spawning cue flows, without
4 unacceptable impacts on human considerations (similar to what is shown on the right
5 side of Table 48. If repeated implementation at Level 3 were to generate a reliable
6 functional relationship between spawning cue flows and the probability of successful
7 spawning, then together with population modeling and survival estimates for other life
8 history stages, it should be possible to estimate the required scale and frequency of this
9 action at Level 4.

10 4.2.6.6.8 *Level 3 Contingent Actions*

11 Contingent actions will need to take into account all of the lines of evidence for different
12 factors that may affect pallid sturgeon recruitment, as summarized in Section 4.2.1.3.

13 4.2.6.7 *Potential Effects of bird actions on pallid sturgeon*

14 A management action for any one objective along the Missouri River has the potential to
15 affect other objectives, especially if an action involves changes to reservoir operations.
16 USGS has completed a preliminary evaluation of pallid sturgeon sensitivity to potential
17 bird-management actions by looking at how ESH flow pulses would affect pallid
18 sturgeon food-producing and foraging habitats (using the IRC habitat criteria defined in
19 section 4.2.6.3.2; Robb Jacobson, pers. comm.) . These habitats are key components of
20 IRCs and are thought to be critical to growth and survival of age-0 pallid sturgeon. Fall
21 and spring ESH pulse flows (without low summer flow components) resulted in a
22 modest gain (about 10%) in only food-producing habitats and only in a restored
23 upstream reach where the flow regime is strongly linked to releases from Gavins Point
24 Dam. Food-producing habitats were insensitive to ESH flows in downstream reaches
25 where flows are not strongly regulated by releases from Gavins Point Dam and foraging
26 habitats were insensitive to ESH flow releases in all cases. Food-producing habitats were
27 also insensitive to ESH flow pulses in channelized (non-restored) reaches, upstream and
28 downstream. Spring ESH pulses resulted in about a 10% increase in qualifying pallid
29 sturgeon spawning cues (that is, doubled flows above navigation support in May).
30 Though this comparison was limited to just a few sites, it provides a preliminary
31 assessment which suggests that effects of ESH flows on pallid sturgeon habitats could be
32 quite minor. Table 50 provides a qualitative assessment of other actions.

1 Table 50 Preliminary and qualitative assessment of the effects of bird actions on pallid sturgeon habitats and
 2 populations.

Action	Geographic overlap with action area for fish*	Direct effect on fish habitat	Direct effect on fish reproduction or survival	Effects on ability to implement fish management actions (other than budget)
Fall and spring ESH flow pulses	Overlap with potential spawning areas downstream of Gavins Point Dam; far upstream of most IRCs (Figure 36)	Spring pulses could possibly assist pallid sturgeon in upstream movement and aggregation for spawning. (10% increase in qualifying spawning cue pulses) Analysis of 2 sites shows neutral or positive effects on IRCs (see text)	Spring pulses likely to be either neutral or positive effect on spawning success and survival of age-0 fish; Fall pulses unlikely to influence reproduction	Unlikely. Spring ESH flows have somewhat different attributes from the ideal spawning cue flow; the latter would only occur at least 9 years post-ROD; may not be implementable in the same year; an ESH spring pulse might use stored water then unavailable for spawning cue.
Habitat conditioning flows	Overlap with potential spawning areas downstream of Gavins Point Dam; far upstream of most IRCs (Figure 36)	Unlikely, as these flows are lower magnitude than fall and spring ESH flow pulses, which showed neutral or positive effects.	Unlikely given that magnitude is lower than fall and spring ESH pulses, which showed neutral or positive effects.	Unlikely given that magnitude is lower than fall and spring ESH pulses.
Vegetation removal	No.	No.	No.	No.

Action	Geographic overlap with action area for fish*	Direct effect on fish habitat	Direct effect on fish reproduction or survival	Effects on ability to implement fish management actions (other than budget)
Low flow management and lowered flows to reduce take	Overlap with potential spawning areas downstream of Gavins Point Dam; far upstream of most IRCs (Figure 36)	Low flow management would occur after pallid sturgeon spawning, and is unlikely to affect spawning habitat. Effects on IRCs are variable and include increases in foraging habitats in channelized reaches, increases in food-producing habitat in upstream reconfigured reaches, and decreases in food-producing habitats in both upstream and downstream reaches.	No effects on spawning due to differences in timing. May increase age-0 survival through increases in foraging habitat and food-producing habitat. First assess potential for effects on IRC habitat (if nil, then don't need to evaluate effects on survival).	Not in the year of implementation. Storing or releasing water from reservoirs might affect operational flexibility for spawning cue flows in subsequent year.
Mechanical ESH creation and augmentation of sandbars	Limited overlap possible from Gavins Point Dam to Ponca, NE. ESH located in areas of low river energy, whereas spawning habitats would be in areas of high river energy. ESH construction is hundreds of miles upstream of IRCs	Unlikely due to low spatial overlap. Also, addition of sand for ESH replaces natural supply.	Very unlikely.	No.
Reservoir habitat creation	No overlap.	No – pallid sturgeon do not use reservoirs	No.	No.
Reservoir level management	No direct spatial overlap with range of pallid sturgeon.	Unlikely. Possible, through low summer flow effects on IRCs described above. Should be evaluated further to assess how reservoir level management may affect flows in IRCs.	Possible. First assess effect on habitat.	Reservoir level management could affect storage available for spawning cue flow actions and flows in IRCs, especially low summer flows.

Action	Geographic overlap with action area for fish*	Direct effect on fish habitat	Direct effect on fish reproduction or survival	Effects on ability to implement fish management actions (other than budget)
Population protection measures	No.	No.	No.	No.
Off-channel habitat creation	No overlap, as spawning habitat is in channel, and IRCs are much further downstream	No.	No.	No.

1

2 If low summer flows are added to consideration, the potential interactions between bird
 3 and fish actions increase. Low summer flows as modeled to decrease take of bird nests
 4 increased availability of foraging habitat in the upper channelized reaches by as much as
 5 30% and the lower channelized reached reaches by 10%; IRC-qualifying habitats in
 6 reconfigured reaches were not sensitive to low summer flows. Low summer flows
 7 increased food-producing habitat by 20% in the upstream reconfigured reaches but the
 8 food-producing habitats in the downstream reaches were insensitive. Channelized
 9 reaches, both upstream and downstream, showed a 10% decrease in food-producing
 10 habitats with low summer flows.

11 **4.3 Implement**

12 **4.3.1 Implementation Plan**

13 Figure 82 and Figure 82 summarize the current implementation schedules for the
 14 actions described above in sections 4.2.5 and 4.2.6, and the associated components at
 15 Levels 1, 2 and 3 (in the order of presentation of each of these actions). These schedules
 16 build on the plans presented by the USFWS and USACE (2015), and have been updated
 17 to reflect both the preferred alternative and current USFWS priorities and timelines, as
 18 well as joint USFWS and USACOE work on prioritization of Level 1 and Level 2
 19 activities, described in Appendix F.

20 Figure 83 and Figure 84 provide the currently proposed schedule for all Level 1 and
 21 Level 2 components in the Upper and Lower Missouri River (respectively), for the first
 22 five years after the ROD, based on the prioritization described in Appendix F. The longer
 23 term schedule for Level 1 and Level 2 activities is presented in Appendix F. The schedule
 24 will require a well-funded and focused surge in research activity conducted by multiple
 25 research teams that work in close coordination (see Appendix F).

- 1 As noted in section 4.2.1 summarizing the Lower Missouri River Pallid Sturgeon
 2 Framework (USFWS and USACE 2015), the timeframe for implementation may be
 3 adjusted as knowledge is gained from Level 1, 2 and 3 actions, hypotheses are tested,
 4 and the likelihood of biological benefits is better understood. Budget allocations may
 5 also affect the timing of particular activities. The rationale for any adjustments in
 6 schedule should be well documented.

	2016	2017	2018	2019	2020	2021	2022	2023	2024	2025	2026	2027	2028	2029	2030	2031	2032
Big Question 1: Spawning Cues																	
Level 1																	
C1 Design complementary passive/active telemetry network																	
C2 Opportunistic tracking of reproductive behaviors																	
C3 Mesocosm experiments, reproductive behaviors																	
Big Question 2: Flow Naturalization and Productivity																	
Level 1																	
C1 Engineering models, interactions with authorized purposes																	
C2 Screening: limitations of food or forage habitats																	
C3 Field studies along gradients, food and forage habitats																	
C4 Mesocosm studies: quantitative habitat – survival relations																	
Big Question 3: Temperature manipulations at Fort Peck																	
Level 1																	
C1 Screening: Feasibility, modeling of effects																	
C2a Screening: is food limiting to age-0 survival?																	
C2b Are Lake Sakakawea conditions limiting to age-0 survival?																	
C3a Field gradient, temperature and food production																	
C3b Field experiment drift/dispersal advection/dispersion validation																	
C4a Mesocosm studies: temperature, food, survival relations																	
C4b Development rates of embryos, free embryos, larvae																	
Big Question 4: Sediment bypass																	
Level 1																	
C2 Mesocosm study of turbidity-limited survival																	
C3 Mesocosm study of turbidity-limited survival rates																	
Big Question 5: Passage, drift, and recruitment																	
Level 1																	
C1a Model integration, drift and development																	
C1b Modeling location and rate of change of headwaters																	
C2a Patchiness of anoxic zone																	
C2b Spawning habitat distribution on the Yellowstone River																	
C3 Field experiment drift/dispersal, modeling of advection/dispersion validation																	
C4 Mesocosm studies to quantify transport																	
Level 2																	
C5 Engineering studies for effects of low flows																	
C6a Drift experiments, Fort Peck flows and drawdowns																	
C6b Adult translocation experiment, Yellowstone																	
Big Question 6: Population Augmentation																	
Level 1																	
C1 Engineering feasibility hatchery needs, facilities, operations																	
C2 Retrospective study survival linked to hatchery operations																	
C3 Simulation models, population sensitivity to size, health, genetics																	
Level 2																	
C4 Field experimentation with varying size, location of stocking																	
Level 3																	
Stocking																	
Technical Development: Modeling and Monitoring Needs																	
Adaptive design and optimization of population monitoring																	
Continued integration and refinement of population model																	
Research: contingency, outreach, reporting																	
Research contingency for basic science, surprises																	
Reporting and outreach																	

8 Figure 81. Current schedule for implementation of actions in the Upper Missouri River, revised from USFWS
 9 and USACE (2015) to reflect the preferred alternative and current USFWS priorities and timelines, and
 10 described in sections 4.2.5 of this report. Arrows represent flexibility in the timing of implementation. This
 11 figure is an illustration of the intended implementation schedule. There may be further adjustments in the
 12 schedule. In-river actions at Level 2 and Level 3 are shown in bolded blue text.

	2016	2017	2018	2019	2020	2021	2022	2023	2024	2025	2026	2027	2028	2029	2030	2031	2032
Big Question 1: Spawning Cues																	
Level 1																	
C1 Design complementary passive telemetry network																	
C2 Opportunistic tracking of reproductive behaviors																	
C3 Mesocosm experiments, reproductive behaviors																	
Level 2																	
C5 Experimental flow releases, Gavins Point														if req'd			
Big Question 2: Temperature Control																	
Level 1																	
C1 Model water temperature management options, Ft. Randall																	
C2 Field studies temperature and reproductive behaviors,																	
C3 Mesocosm studies temperature and reproductive behaviors																	
Big Question 3: Food and Forage																	
Level 1																	
C1 Screening: limitations of food or forage habitats																	
C2 Technology development for IRC sampling, modeling, measurement																	
C3 Field studies along gradients, food and forage habitats																	
C4 Mesocosm studies: quantitative habitat – survival relations																	
Level 2																	
C5 Design studies for IRC experiments																	
C6 Build IRCs in staircase design & refurbish SWHs																	
Level 3																	
Implement more IRCs if found to be successful																	
Big Question 4: Drift Dynamics																	
Level 1																	
C1 Technology development surrogate particles, particle tracking																	
C2 Resilience, stamina in turbulent flows (lab or mesocosm study)																	
C3 Field studies on free embryo exit paths																	
C4 Field gradient study, age-0 survival and complexity																	
C5 Free embryo transport to Mississippi River																	
C6 Field experiments with particle tracking, embryos, models																	
Big Question 5: Spawning Habitat																	
Level 1																	
C1 Study of functional spawning habitat, Yellowstone River																	
C2 Field gradient study, habitat conditions LMOR																	
C3 Mesocosm studies on spawn conditions, behaviors																	
Level 2																	
C4 Engineering studies for sustainable design																	
C5 Manipulative field experiment for spawning habitat																	
Level 3																	
If successful and appropriate, expand spawning habitat																	
Big Question 6: Population Augmentation																	
Level 1																	
C1 Engineering feasibility hatchery needs, facilities, operations																	
C2 Retrospective study survival linked to hatchery operations																	
C3 Simulation models, population sensitivity to size, health, genetics																	
Level 2																	
C4 Field experimentation with varying size, location of stocking																	
Level 3																	
Stocking																	
Technical Development: Modeling and Monitoring Needs																	
Adaptive design and optimization of population monitoring																	
Continued integration and refinement of population model																	
Research: contingency, outreach, reporting																	
Research contingency for basic science, surprises																	
Reporting and outreach																	

Figure 82. Current schedule for implementation of actions in the Lower Missouri River, revised from USFWS and USACE (2015) to reflect the preferred alternative and current USFWS priorities and timelines, and described in section 4.2.6 of this report. Arrows represent flexibility in the timing of implementation. This figure is an illustration of the intended implementation schedule. There may be further adjustments in the schedule. In-river actions at Level 2 and Level 3 are shown in bolded blue text.

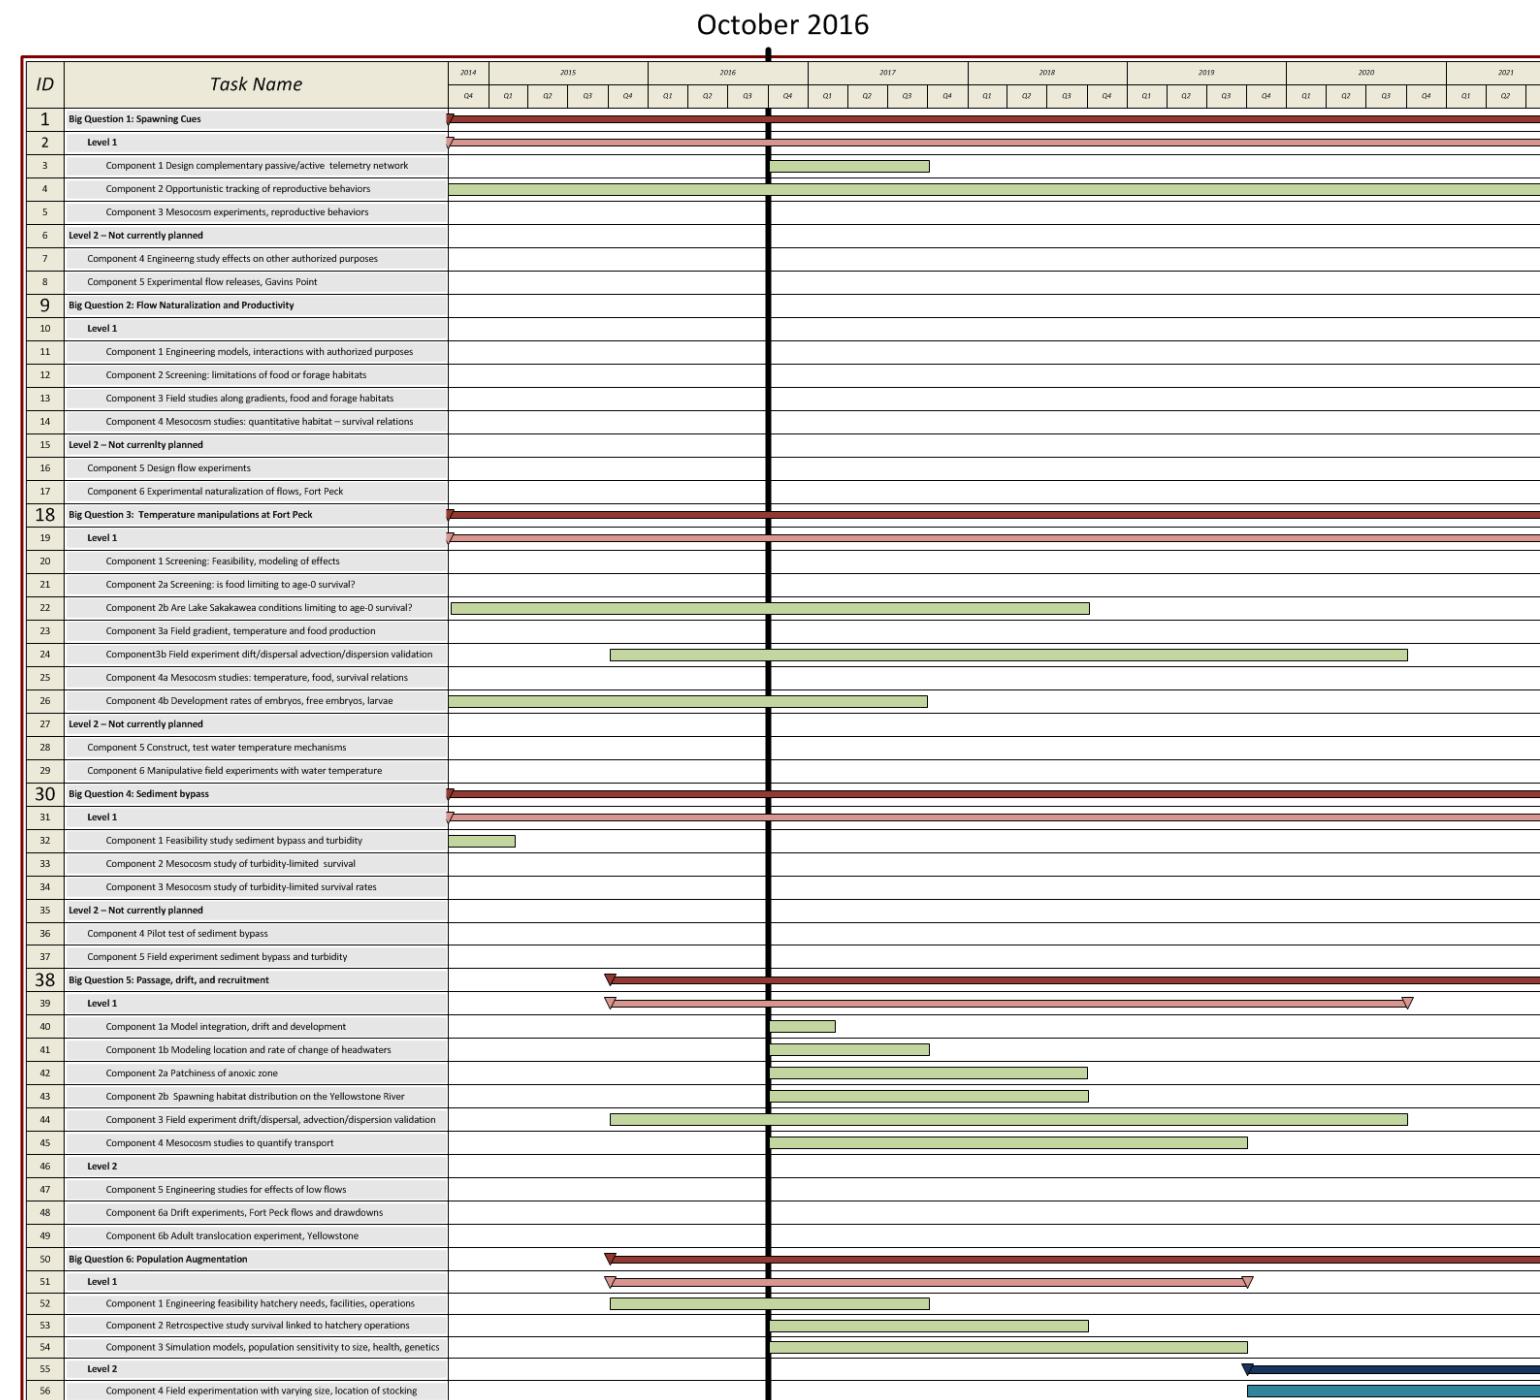

Figure 83. Proposed schedule for all science and AM components (Levels 1 and 2) in the Upper Missouri River during the first 5 years post ROD.

October 2016

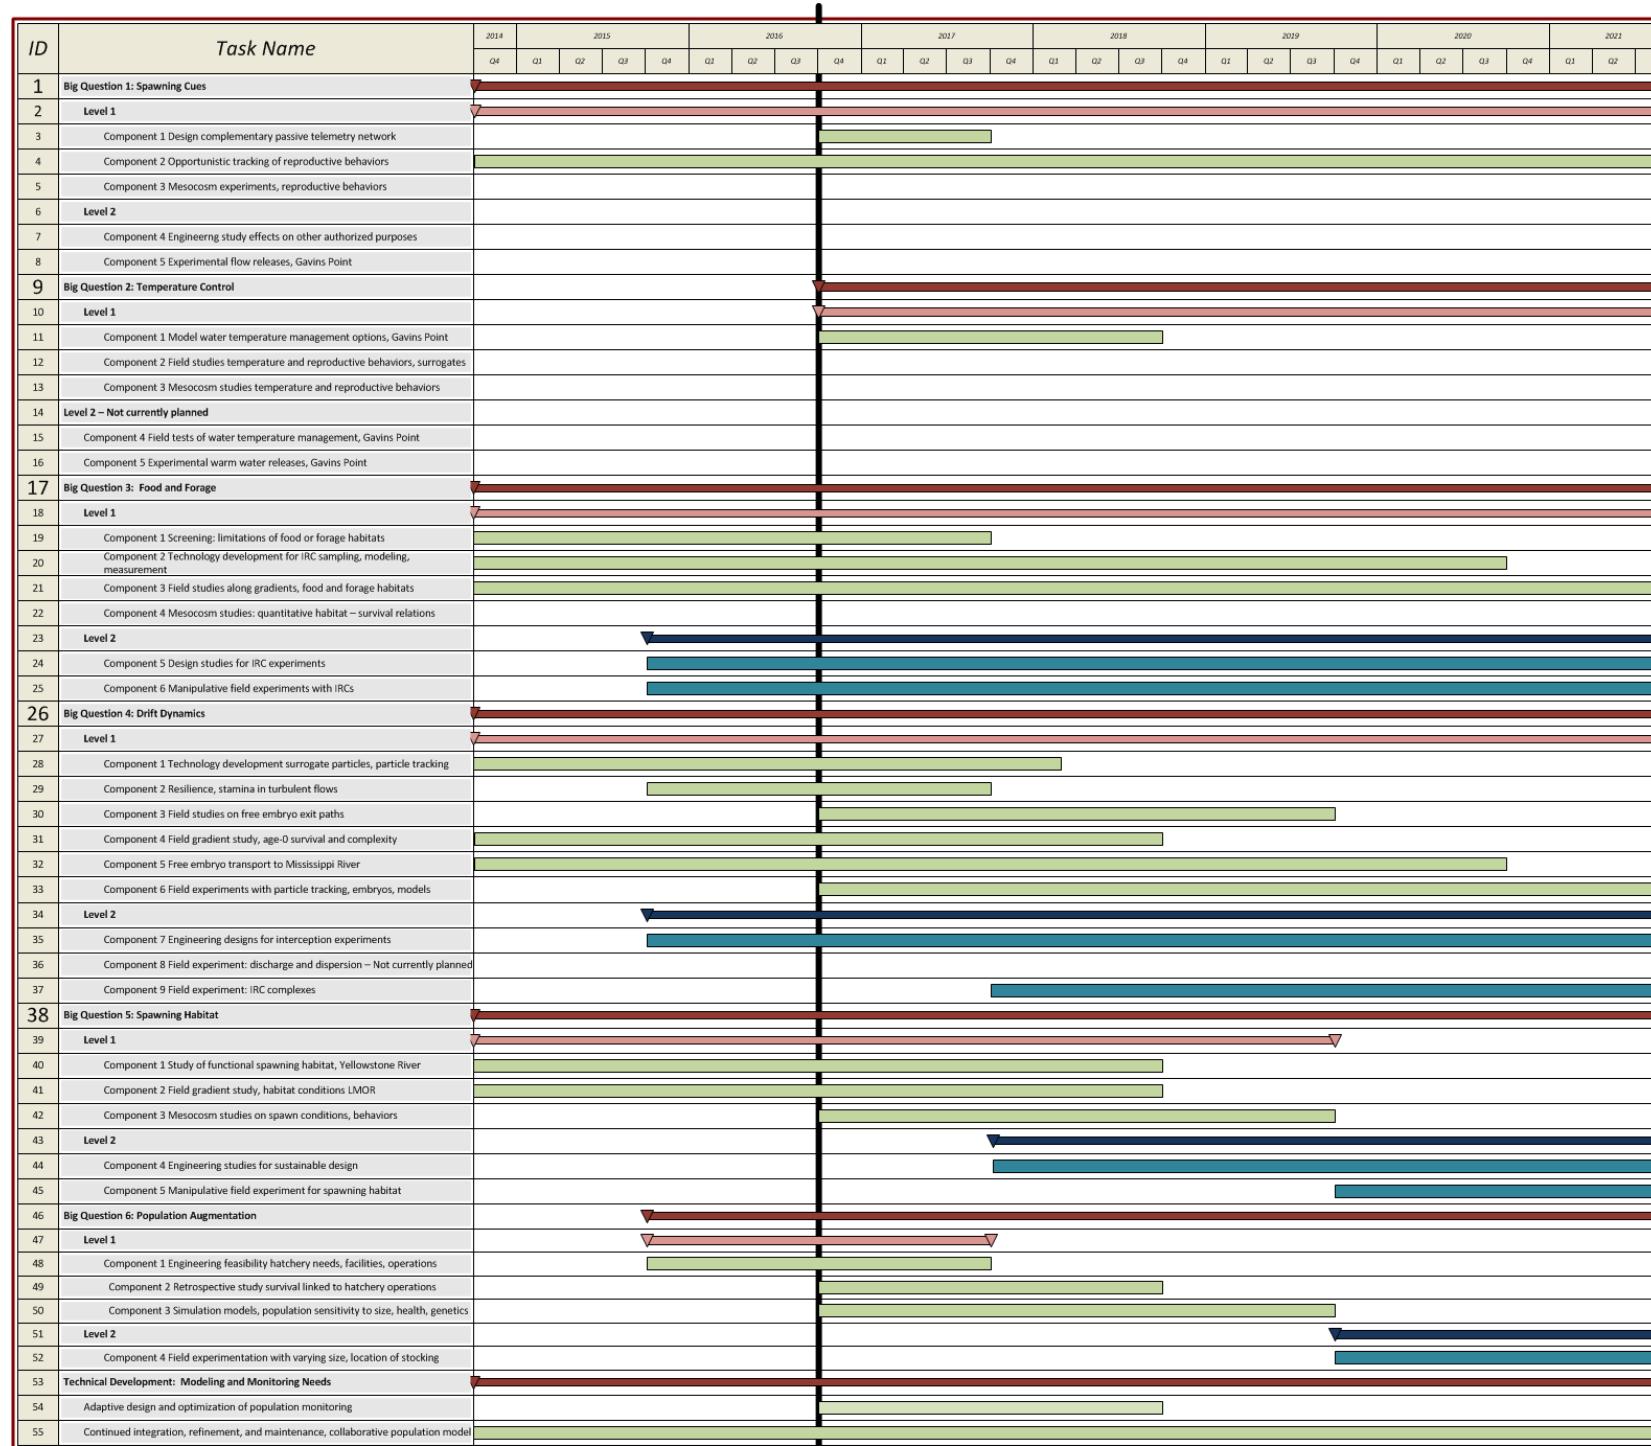

Figure 84. Proposed schedule for all science and AM components (Levels 1 and 2) in the Lower Missouri River, during the first 5 years post ROD.

1 **4.4 Monitor**

2 There are 3 types of monitoring that need to be conducted as the AM Plan proceeds:

- 3 • Implementation Monitoring – did the action get successfully completed as intended?
- 4 • Process / Action Effectiveness Monitoring – is there an ecological response that will
- 5 increase survival or appropriately inform the next Level of implementation towards
- 6 achieving increased survival?
- 7 • Population Monitoring – is the population growing, attaining the right size?

8 Foundational research is required at Level 1 to support all three forms of monitoring,

9 including the design of new protocols, the establishment of monitoring hardware such

10 as stationary telemetry networks, and the development of models and power analyses to

11 test out monitoring protocols and experimental designs.

12 Implementation monitoring is essential to determine if intended actions did in fact

13 occur. This is important to document compliance and essential for cause-effect

14 evaluations of action effectiveness. Scientists need to know where and when a given type

15 of action was present in order to assess whether pallid sturgeon might have been

16 exposed to the effects of that action.

17 Appendix D describes the proposed revisions to current protocols for population

18 monitoring, replacing a catch per unit effort approach with a mark-recapture approach.

19 Population monitoring is a complex issue which will need further review. As explained

20 in Appendix D (section B.1.3), and to be further tested by Level 1 research, there are

21 three broad reasons for improving the current methods of population monitoring:

- 22 1. Current methods of population monitoring rely on catch per unit effort (CPUE),
- 23 which is confounded by factors that affect catchability, like changes in flow, does
- 24 not provide accurate data for model calibration, and in the Lower Missouri River is
- 25 poorly correlated with trends in stocking of hatchery fish;
- 26 2. Mark-recapture estimates of various life history stages will provide much better
- 27 estimates of survival rates and abundance for use in the collaborative population
- 28 model, which will be used to assess the potential population-scale benefits of Level 2
- 29 and Level 3 actions. The model will also be used in the revised design of the
- 30 population monitoring protocol, so that the monitoring protocol and model structure
- 31 will be well integrated.
- 32 3. Accurate estimates of population size will be an important input to decisions on
- 33 stocking (which need to account for density dependence, and use population
- 34 abundance as an integrative measure of the effectiveness of stocking), and ultimately
- 35 on recovery (which requires an estimate of the population size, not just its trend).

1 Appendix E contains references to the current monitoring protocols for process /
 2 effectiveness monitoring; these protocols need to be reviewed, applying the principles
 3 outlined in Appendix E. Table 51 summarizes the metrics to be used for each type of
 4 monitoring for each Level 2 and Level 3 action described in sections 4.2.5 and 4.2.6.
 5 Appendix K provides a summary of metrics used to detect the effectiveness of various
 6 actions, as well as metrics used for tracking the status and trends of the pallid sturgeon
 7 population.

8 Table 51. Summary of metrics to be used for implementation, process / action effectiveness and population
 9 monitoring for each Level 2 and Level 3 action described in sections 4.2.5 and 4.2.6. Hypotheses listed in first
 10 column (e.g., H8, H9) are those most relevant to the action, as discussed in section 4.2. The section listed in
 11 the first column provides a more detailed description of metrics associated with a given action; other metrics
 12 are listed in Appendix K.

Level 2 / 3 Action	Implementation monitoring	Process monitoring	Population monitoring
Augmentation [H8, H9] [H20, H21]	-meeting stocking targets by age, hatchery and release location -meeting health criteria in hatchery -fulfilling experimental design of Level 2 management experiments	- Number, size, age, location, habitat and origin of released and captured pallid sturgeon -fish condition, genetics, disease levels -density of hatchery-origin free embryos and larvae found in preferred rearing habitats	-estimated survival probabilities of hatchery fish to age-1,2 and 3, by stocked size, age, hatchery of origin, release location -modelled long term change in population based on survival probabilities of hatchery origin fish (e.g., probability of quasi extinction, population growth rates) - effective population size
Intake Dam [H7]	-safe upstream and downstream passage of adults -safe downstream passage of embryos, free embryos and larvae	-density of free embryos and larvae found in preferred rearing habitats (and not headed for anoxic zones of Lake Sakakawea) -estimated improvement in spawning and recruitment from passage around Intake Dam (same metrics for monitoring spawning as for spawning cue flows)	-modelled long term change in population based on estimated proportional increase in successful spawning due to passage around Intake Dam (if such an increase occurs)
IRC Habitat [H17, H18, H19]	-“effective acreage” (acre-days of available IRC habitat/year)	- habitat metrics based on measures of depths, velocities, substrate, habitat complexity - trends in % SWH area with suitable habitat after refurbishment to IRCs -CPUE and Pr (apparent presence) at meso-habitat and project level; - production of food/area -fish condition (% empty/full stomachs; genetics; lipid	-survival of hatchery-reared first-feeding pallid sturgeon larvae in IRCs, refurbished SWH, thalweg, and to age 1 -population size structure analysis (length-frequency distributions of age-1+ fish)

Level 2 / 3 Action	Implementation monitoring	Process monitoring	Population monitoring
		content; length frequency distribution of age-0 fish) and bioenergetics modeling	
Spawning Habitat [H16] Metrics: section 4.2.6.5.5	-# and area of spawning sites created with suitable characteristics (depth, velocity, substrate, and derivative hydraulic variables)	- confirmation of site quality -telemetry data showing relative selection of created spawning sites vs. control sites -attraction/specificity of adults to different spawning substrates; site confirmation that eggs are not buried -confirmation of spawning (see evidentiary framework on spawning cue flows - Table 48)	-modelled long term change in population based on estimated proportional increase in successful spawning due to creation of high quality spawning habitat (if such an increase occurs) - field monitoring of recruitment to age-1,2,3
Spawning Cue Flows [H11] Metrics: section 4.2.6.5.5	-flow monitoring to check whether spawning cue flow had expected timing, magnitude, and longitudinal spatial distribution	-movement and aggregation of spawning males and females in response to spawning cue flow -multi-receiver, 3D telemetry and acoustic video to confirm egg release events - male: female ratios in spawning aggregations (if sufficient # males tagged) -confirmation of female spawning through captured downstream eggs and embryos, and recapture of spawned females	-mesocosm and field-inferred benefit of achieved pulse -modelled long term change in population based on estimated proportional increase in successful spawning due to spawning cue (if such an increase occurs) - field monitoring of recruitment to age-1,2,3 (delayed metric reflecting the cumulative effect of all actions, other stressors and natural variability)

1 **4.5 Evaluate**

2 **4.5.1 Evaluation Methods**

3 Table 52 summarizes the methods used to evaluate the effectiveness of various actions,
4 applying the metrics that are summarized above in Table 41, and listed in Appendix K.
5 Each action is broken down into a series of key questions, and the evaluation methods
6 used to answer each question. The first column of Table 47 includes hyperlinks to the
7 parts of sections 4.2.5 and 4.2.6 describe the details of the experimental designs and
8 evaluation methods for each action, and its associated key questions.

1 Table 52. Summary of methods for evaluating the effectiveness of Level 3 actions. Some of these actions also
 2 have Level 2 management experiments. Hypotheses listed in first column (e.g., H8, H9) are those most
 3 relevant to the action, as discussed in section 4.2, and listed in Table 43 and Table 44. [Upper]=Upper
 4 Missouri River; [Lower] =Lower Missouri River. L2=Level 2. L3=Level 3. The sections listed in the first column
 5 provide more details on the experimental design for each action; Appendix K provides a list of metrics for each
 6 management action, as well as status and trend monitoring.

Action	Question [Level, Location]	Methods of evaluating action effectiveness
Augmentation [H8, H9] [H20, H21]	Is the region releasing the optimal sizes of hatchery fish (i.e., fingerlings or yearlings)? [L2, Lower]	Use a staircase design over multiple years to compare the survival probabilities of fish stocked as fingerlings vs. yearlings, while accounting for the hatchery of origin and other factors affecting survival rates. See list of metrics in section 4.4
Experimental design: section 4.2.5.1.6	Is the region releasing fish from the optimal locations? [L2, Upper and Lower] ¹	Compare various metrics (e.g., recapture probabilities, recapture location, condition, survival probabilities) of different groups of marked fish that are released from different locations (e.g., upstream vs. downstream of Intake Dam; Missouri vs. Yellowstone River), and then recaptured at multiple locations and times.
	Is augmentation meeting target survival rates, ensuring a 95% probability of persistence over a 50-year period and supporting positive trends in populations? [L3, Upper & Lower]	Apply the augmentation strategies developed in Level 2 studies, and compare 3-year running averages of various metrics (see augmentation row in Table 9, section 4.4) to established targets, (as informed by Level 1 and Level 2 studies, particularly population modeling studies).
Intake Dam [H7]	Do adult pallid sturgeon migrate upstream past Intake Dam, migrate to spawning sites and aggregate there? [L3, Upper]	Tracking of telemetered adult fish using USGS methods.
Experimental design: sections 4.2.5.2.6 4.2.6.2.4	Do adults of reproductive age spawn successfully in the Yellowstone River above Intake Dam? [L3, Upper]	Post-spawn monitoring of free embryos, larvae, and juveniles (with genotypes traced to parents), at various locations (e.g., downstream of spawning site, downstream of Intake Diversion Dam)
	Are some of the juveniles (age 3+) collected in the Yellowstone River the progeny of tagged adult fish that migrated upstream of Intake Diversion Dam? [L3, Upper]	Monitoring of age 3+ juveniles in Yellowstone River and assessment of genetic parentage
	What are the attributes of selected spawning sites (useful for design of spawning sites in L. Missouri)? [L2/ L3, Upper]	Document site characteristics of spawning locations (e.g., substrate, velocity, water temperature, suspended sediment, cross-section profile)

¹ This and the above question are example questions; the critical uncertainties to be resolved will emerge from the Stocking and Augmentation Plan under development by the Recovery Team.

Action	Question [Level, Location]	Methods of evaluating action effectiveness
	Do free embryos avoid dispersal into Lake Sakakawea? [L3, Upper]	Apply refined advection/dispersion models.
	Does spawning in Yellowstone River above Intake Dam improve the trajectory of the Upper Missouri River population of pallid sturgeon, and suggest that the population has a 95% probability of persistence over a 50-year period? [L3, Upper]	Apply collaborative population model using estimates from above studies for spawning locations above and below Intake Dam (e.g., frequency of spawning, proportion of successful spawning, indices of relative abundance and survival) to assess overall effect on population.
Interception and Rearing Complexes (IRCs) [H17, H18, H19] Experimental design: sections 4.2.6.3.4 4.2.6.4.4	Do free embryos and exogenously feeding larvae leave the thalweg and enter IRCs? [L3, Lower] Is there sufficient food in IRCs for exogenously feeding larvae to grow better and maintain a healthier condition than reference areas and times? ¹ [L3, Lower] Do age-0 fish that occupy IRCs survive better than age-0 fish in reference areas and times? [L3, Lower] What's the population-level effect of improved survival of age-0 fish in IRCs? [L3, Lower] Is food limiting outside of IRC habitats [L3, Lower]	Predicted fate of free embryos from advection/ dispersion models. Testing of these predictions with field monitoring (see below). Staircase design comparisons of IRC habitat sites with reference areas and times, using the metrics listed in Table 9, section 4.4 (e.g., CPUE, probability of apparent presence, food production/area, condition, growth and survival of age-0 fish), and applying covariates to help explain year to year variation (e.g., index of upstream spawning success). Population model projections of the consequences of improved age-0 survival rates.
Spawning Habitat [H16] Experimental design: section 4.2.6.5.6	To what extent does successful spawning occur now? [redesigned PSPAP and other monitoring] Has suitable spawning habitat been created and maintained? [L2/L3, Lower] Are created spawning habitats preferred over other areas by pallid sturgeon in reproductive condition? [L2/L3, Lower] Does successful spawning occur in the created spawning habitat? [L2/L3, Lower] Would creation of more high-quality spawning habitat at Levels 3 and 4 have a significant benefit to the population? [L2/L3, Lower]	Compare metrics listed in Table 51 for the created spawning area(s) (see Figure 77 for possible areas) vs. reference areas (other outside bends used for spawning – see Figure 78) Population model projections of the consequences of creating more spawning habitat
Spawning Cue Flows [H11]	Do spawning cue flows lead to greater aggregations of pallid sturgeon in reproductive condition? [L2/L3, Lower]	Assemble evidence for and against benefits of spawning cue flows from Level 2 mesocosm and gradient studies.

¹ For this to be true, food would need to be a limiting factor that was made less limiting by the creation of IRCs.

Action	Question [Level, Location]	Methods of evaluating action effectiveness
Experimental design: Section 4.2.6.6.6	Do spawning cue flows lead to higher rates of successful spawning? [L2/L3, Lower] Would creation of more spawning cue flows at Levels 3 and 4 have a significant benefit to the population? [L2/L3, Lower]	To the degree possible while accounting for confounding effects, compare metrics listed in Table 9 for years and locations with a strong spawning cue flow vs. years and locations without a spawning cue flow. Population modeling of the consequences of creating more spawning cue flows.

1 4.6 Decide

2 Table 41 (from USFWS and USACE 2015) outlined a series of 5 questions relevant to
 3 decisions regarding each of the factors reviewed in the EA, and whether actions
 4 associated with this factor should be implemented at Level 3:

- 5 • Is this factor limiting pallid sturgeon reproductive and/or recruitment success?
- 6 • Are pallid sturgeon needs sufficiently understood with respect to this limiting factor?
- 7 • Do one or more management action(s) exist that could, in theory, address these
 needs?
- 9 • Has it been demonstrated that at least one kind of management action has a
 sufficient probability of satisfying the biological need?
- 11 • Have other biological, legal, and socioeconomic considerations been sufficiently
 addressed to determine whether or how to implement management actions to Level
 3?

14 At a somewhat broader level, there are three major categories of decisions on pallid
 15 sturgeon (summarized in Figure 62):

- 16 A. Is there enough evidence at Level 1 to proceed with an action at Level 2?
- 17 B. Is there enough evidence at Level 1 and Level 2 to proceed with an action at Level 3?
- 18 C. Have time limits been reached for implementation of Level-3 actions?
- 19 D. Is there enough evidence at Level 3 to proceed with an action at Level 4?

20 The evidence that is used for these decisions includes metrics and decision criteria
 21 *specific to a single action* as well as the accumulating evidence of the *relative amount of*
 22 *support for multiple actions*. An overview of decision criteria is provided in Figure 65.
 23 Metrics and decision criteria pertaining to single actions can be found in Appendix C, as
 24 well as in Table 43 and Table 44 for decisions in categories A and B. Decisions related to
 25 single actions for categories B and C are discussed in the sub-sections on Metrics and
 26 Decision Criteria in section 4.2. For evidence on the *relative amount of support for*
 27 *multiple actions*, this chapter also includes decision trees for recruitment in the Upper
 28 Missouri river (Figure 63), recruitment in the Lower Missouri River (Figure 64) and

1 spawning habitat (Figure 78). The collaborative population model (described in
2 Appendix D) will be used to integrate information from Level 1 through 3 studies to
3 provide rank order estimates of the relative benefits of different actions in helping with
4 the recovery of pallid sturgeon.

5 Evidence is largely about understanding cause and effect. That is, does the cause of
6 implementing an action (or multiple actions) to improve reproduction, growth or
7 survival of pallid sturgeon have a measurable and desired effect on one or more life
8 history stages? How strong is the overall weight of evidence from multiple sources?
9 Previous studies that have retrospectively assessed multiple lines of evidence for
10 potential causes of changes in biota (Forbes and Callow 2002; Burkhardt-Holm and
11 Scheurer 2007, Diefenderfer et al. 2011, Marmorek et al. 2011) have generally looked at
12 four different factors: 1) a *plausible mechanism* by which the cause could create a
13 biological effect (which makes sense scientifically); 2) the biota are *exposed* to the
14 causative factor (i.e., the cause overlaps the distribution of the species in space and
15 time) ; 3) changes in biota are *correlated in space and time* with the causative factor;
16 and 4) there is *experimental evidence* that the causative factor can create the
17 hypothesized effect (e.g., from laboratory, mesocosm or field experiments, or natural
18 events that are opportunistic experiments). Diefenderfer et al. 2016 provide a more
19 comprehensive conceptual framework for evaluating the evidence for cumulative effects
20 in areas subjected to ecosystem restoration actions.

21 Table 53 summarizes the criteria for deciding whether to move from a Level 2 action to a
22 Level 3 action, and whether to move from Level 3 to Level 4 (i.e., decision categories B
23 and C). These criteria are based on the ‘Decision criteria’ parts of section 4.2, and the
24 decision-relevant questions from Table 52 (most of the questions listed above). The
25 colored columns to the right of Table 53 show five possible answers to each question,
26 drawn from the approach used in the Platte River Recovery Implementation Program
27 (PPRIP 2014), and similar to other approaches used for weight of evidence syntheses
28 (e.g., Peterman et al. 2010, Marmorek et al. 2011). Details on decision criteria are
29 provided in the sections listed in the first column of Table 53. Chapter 2 of this AMP
30 describes the governance process for the Missouri River Management Plan.

31
32

1 Table 53. Summary of decision criteria to be applied to the currently proposed set of Level 3 actions.
 2 Hypotheses listed in first column are those most relevant to the action, as discussed in section 4.2. The
 3 sections listed in the first column provide more details on the decision criteria for each action. Appendix K
 4 provides a list of metrics for each management action, as well as status and trend monitoring.

Level 2 / 3 Action [Hypothesis]	Decision Criteria / Questions	Answers				
		Clearly NO. 	Likely NO. 	Inconclusive 	Likely YES. 	Clearly YES. 
Augmentation [H8, H9] [H20, H21]	Is augmentation meeting target survival rates, ensuring a 95% probability of persistence over a 50-year period and supporting positive trends in upper and lower river populations? [L3, Upper and Lower]					
Decision criteria: sections 4.2.5.1.7 and 4.2.6.2.5	Is there a self-sustaining population in excess of 5000 fish in each management unit?					
Intake Dam [H7]	Do adult pallid sturgeon migrate upstream past Intake Dam, migrate to spawning sites and aggregate there? [L3, Upper]					
Decision criteria: section 4.2.5.2.7	Do adults of reproductive age spawn successfully in the Yellowstone River above Intake Dam? [L3, Upper]					
	Are some of the juveniles (age 3+) collected in the Yellowstone River the progeny of tagged adult fish that migrated upstream of Intake Diversion Dam? [L3, Upper]					
	Do free embryos avoid dispersal into Lake Sakakawea? [L3, Upper]					
	Does spawning in Yellowstone River above Intake Dam improve the trajectory of the Upper Missouri River population of pallid sturgeon, and suggest that the population has a 95% probability of persistence over a 50-year period? [L3, Upper]					
Interception and Rearing Complexes (IRCs) [H17, H18, H19]	Do free embryos and exogenously feeding larvae leave the thalweg and enter IRCs? [L3, Lower]					
	Is there sufficient food in IRCs for exogenously feeding larvae to grow better and maintain a healthier condition than in reference areas and times? [L3, Lower]					

Level 2 / 3 Action [Hypothesis]	Decision Criteria / Questions	Answers				
		Clearly NO. 	Likely NO. 	Incon- clusive 	Likely YES. 	Clearly YES. 
Decision criteria: sections 4.2.6.3.6 and 4.2.6.4.6	Do age-0 fish that occupy IRCs have a higher survival probability than age-0 fish in reference areas and times? [L3, Lower]					
	What's the population-level effect of improved survival of age-0 fish in IRCs? [L3, Lower]					
Spawning Habitat [H16] Decision criteria: section 4.2.6.5.7	Has suitable spawning habitat been created and maintained? [L2/L3, Lower]					
	Are created spawning habitats preferred over other areas by pallid sturgeon in reproductive condition? [L2/L3, Lower]					
	Does successful spawning occur in the created spawning habitats? [L2/L3, Lower]					
	Would creation of more high-quality spawning habitat at Level 4 have a significant benefit to the population? [L2/L3, Lower]					
Spawning Cue Flows [H11] Decision criteria: section 4.2.6.6.7	Do spawning cue flows lead to greater aggregations of pallid sturgeon in reproductive condition? [L2/L3, Lower]					
	Do spawning cue flows lead to higher rates of successful spawning? [L2/L3, Lower]					
	Would creation of more spawning cue flows at Levels 3 and 4 have a significant benefit to the population? [L2/L3, Lower]					

1 **5 Human Considerations**

2 This chapter is organized according to the five steps of the AM cycle introduced in
3 Chapter 1:

- 4 1. **Assess** (Section 5.2), which provides objectives and for Human Considerations
5 (HCs) and summarizes the related results of the MRRMP-EIS analyses;
- 6 2. **Plan and Design** (Section 5.3), which outlines the management actions under
7 the MRRP and the approach for addressing HCs under the AM Plan;
- 8 3. **Implement** (Section 5.4), which describes the operational decision making and
9 Water Management functions for the System;
- 10 4. **Monitor** (Section 5.5), which summarizes the concerns, metrics, and monitoring
11 strategies for HCs;
- 12 5. **Evaluate** (Section 0), which summarizes the evaluation of monitoring results,
13 new information, model updates and validation, and the use of ancillary
14 information and unexpected events and the role of the HC Team; and
- 15 6. **Decide** (Section 5.7), which summarizes key management decisions and
16 associated tools including predictive models, decisions to reevaluate alternative
17 management actions, adjustments to operations to minimize HC impacts, and
18 associated processes under the MRRP.

19

20 Associated appendices include Appendix A (Protocols and procedures for decisions),
21 Appendix H (Monitoring protocols for Human Considerations) and Appendix I
22 (Assessments for Human Considerations).

23 **5.1 Background**

24 The USACE operates the Missouri River Mainstem Reservoir System (System), which
25 includes six dams, in accordance with the Master Water Control Manual (Master
26 Manual) to serve eight Congressionally authorized purposes; flood control, navigation,
27 hydropower production, water supply, water quality, irrigation, recreation and fish and
28 wildlife. Combined, operation of the System and the BSNP annually generate
29 approximately \$2.2 billion (FY2015 dollars) in benefits to the nation (see Chapter 1 of
30 the MRRMP-EIS). In operating the System for these purposes, the USACE must comply
31 with all applicable laws and regulations, including the ESA. The Missouri River Bank
32 Stabilization and Navigation Project (BSNP) was designed to provide reliable Missouri
33 River navigation. The ESA requires the USACE to avoid jeopardizing the continued
34 existence of any federally listed species when operating the BSNP.

1 The Missouri River has been modified to meet a variety of HC interests for more than a
2 century. Physical works such as dams created the opportunity to manage - to some
3 degree - the flow of water through the mainstem. From the beginning, management
4 operations sought to improve matters for a range of goals. The first efforts were
5 concerned mainly with issues of flood control and navigation, but with the expansion of
6 infrastructure in the 1940s as a result of the 1944 Flood Control Act, the wider range of
7 Congressionally authorized project purposes identified above also needed to be satisfied.
8 Addressing these needs along with legal obligations to Tribes, endangered species and
9 other factors is the challenge in conventional operation of the System.

10 Because some priorities for water use are mutually contradictory, the need to find a
11 reasonable balance among HC interests has therefore always been central to the
12 operation of the System. In 1960, the previous decade's implicit operational rules for
13 doing so were encoded into a Missouri River Mainstem Reservoir System Master Water
14 Control Manual, commonly referred to as the Master Manual (Ferrell 1993). The Master
15 Manual was subsequently revised during the 1970s, and again in March 2004, following
16 a 14-year period (1989-2004) of public involvement, to include more stringent drought
17 conservation measures. The most recent revision of the Master Manual occurred in
18 March 2006 to include technical criteria for a bimodal spring pulse from Gavins Point
19 (USACE 2006).

20 The USACE, in coordination with the USFWS, undertook the MRRMP-EIS to develop a
21 suite of actions that meets USACE ESA responsibilities for the piping plover, interior
22 least tern, and pallid sturgeon. The focus of alternative development for this EIS was on
23 actions necessary to avoid jeopardy to these species in light of a recent synthesis and
24 analysis of scientific information accrued over roughly the past decade. The EIS also
25 considered the effects of proposed actions on Human Considerations (HCs) – the term
26 used in the Missouri River Recovery Program (MRRP) to address the interests of
27 stakeholders. These include the authorized purposes as well as the many other services
28 afforded by the system. Minimizing the impacts to HC_s while fulfilling the requirements
29 of the ESA is a fundamental objective for the MRRP. This chapter discusses how HC_s
30 were addressed during the EIS and how they will be considered during implementation
31 of the AMP to achieve this objective.

1 **5.2 Assessing Human Considerations**

2 **5.2.1 Objectives**

3 Minimizing the impacts to HCs while fulfilling the requirements of the ESA is a
4 fundamental objective for the MRRP.

5 **5.2.2 How HCs are considered in operational decision making**

6 The Master Manual is the guidance document that helps determine how water should be
7 released from the six reservoirs for the benefit of the entire Missouri River basin.
8 Human considerations were integral to the development of the Master Manual with the
9 goal of serving the eight Congressionally-authorized project purposes (see below),
10 meeting the contemporary needs of the basin, fulfilling the USACE's responsibilities to
11 the Tribes, and complying with relevant environmental laws, including the ESA.

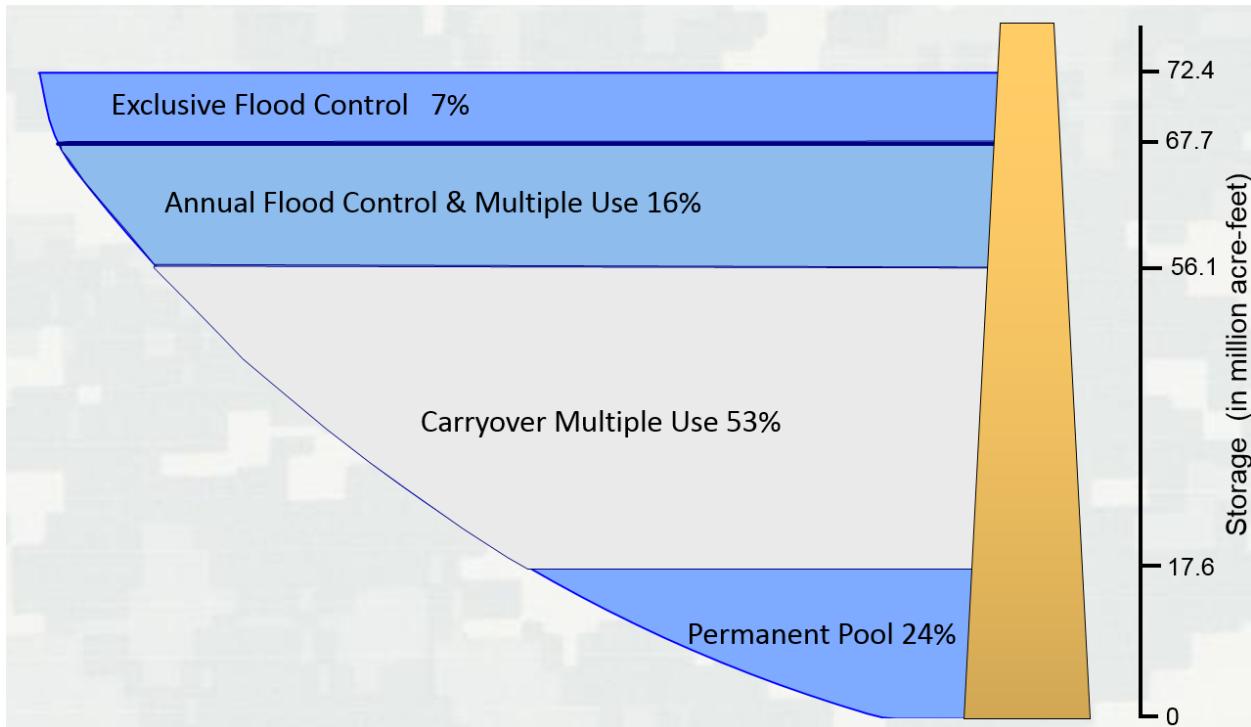

12 The reservoir system is designed to capture spring and summer runoff to provide flood
13 risk management and allows the USACE to manage releases throughout the year to
14 accommodate the other seven authorized purposes: navigation, irrigation, water supply,
15 hydropower, fish and wildlife, recreation, and water quality.

16 The six USACE dams spanning the Missouri River control runoff from approximately
17 half of the basin. The combined storage capacity of all six System reservoirs is 72.4
18 MAF, about three times the annual runoff into the System above Sioux City. This high
19 ratio of storage capacity to runoff lends an unusual degree of flexibility to the regulation
20 of the multipurpose reservoir system. The System is also unique in the fact that 88
21 percent of the combined storage capacity is in the upper three reservoirs of Fort Peck,
22 Garrison, and Oahe.

23 The System storage capacity is divided into four unique storage zones for regulation
24 purposes (see Figure 85). The bottom 24 percent of the total System storage capacity
25 comprises the permanent pool designed for sediment storage, minimum fisheries, and
26 minimum hydropower heads. The largest zone, comprising 53 percent of the total
27 storage capacity, is the carryover-multiple use zone which is designed to serve all project
28 purposes, though at reduced levels, through a severe drought like that of the 1930's.

29 The annual flood control and multiple use zone - occupying 16 percent of the total
30 storage capacity - is the desired operating zone of the System. Ideally, the System is at
31 the base of this zone at the start of the spring runoff season. Spring and summer runoff
32 is captured in this zone and then metered out throughout the remainder of the year to
33 serve the other project purposes, returning the reservoirs to the base of this zone by the

- 1 start of the next runoff season. The top seven percent of the System storage capacity is
 2 the exclusive flood control zone. This zone is used only during extreme floods, and
 3 evacuation is initiated as soon as downstream conditions permit.

4
 5 Figure 85. Missouri River system reservoir storage allocation; values represent cumulative capacity of the six
 6 main-stem reservoirs. Source: <http://www.nwd-mr.usace.army.mil/rcc/reports/pdfs/rcc2015summary.pdf>

- 7 The Water Control Plan, detailed in Chapter VII of the Master Manual, is designed to
 8 achieve the multipurpose objectives of the System. The two primary high-risk flood
 9 seasons are the plains snowmelt season, which extends from late February through
 10 April, and the mountain snowmelt period, which extends from May through July.
 11 Runoff during both of these periods may be augmented by rainfall. The winter ice-jam
 12 flood period extends from mid-December through February. The highest average power
 13 generation period extends from mid-April to mid-October, with high peaking loads
 14 during the winter heating season (mid-December to mid-February) and the summer air
 15 conditioning season (mid-June to mid-August).
- 16 The normal eight-month navigation season extends from April 1st through November
 17 30th during which time System releases are scheduled, in combination with
 18 downstream tributary flows, to meet downstream target flows. Winter releases after the
 19 close of navigation season are much lower, and vary depending on the need to conserve
 20 or evacuate System storage while managing downstream river stages for water supply
 21 given ice conditions. Minimum release restrictions and pool fluctuations for fish

1 spawning management generally occur from April through June. Nesting of the two
2 Federally-protected bird species occurs from early May through mid-August.

3 The water control plan includes the following concepts:

- 4 • the division of the individual system reservoirs into storage zones, as described
5 above
6 • specific technical criteria to define the level of service for navigation and other
7 downstream uses, including winter releases for water supply, and to allow
8 evacuation of stored flood water in a manner that minimizes flood risk
9 • recommended minimum daily flows for water supply, irrigation, and downstream
10 fisheries
11 • guidelines to provide rising reservoir levels for reservoir fish spawning, intra-system
12 unbalancing, and specific technical criteria for a spring pulse from Gavins Point dam
13 for the benefit of the endangered pallid sturgeon
14 • reservoir regulation options for use during the tern and plover nesting season to
15 provide habitat and minimize incidental take.

16
17 These concepts are codified in the Master Manual. Referred to as the “technical
18 criteria”, they are summarized in Missouri River Mainstem Reservoir System - System
19 Description and Regulation (USACE 2007), and presented in Attachment 4 of Appendix
20 A of this AM Plan.

21 Collectively, the specific technical criteria do not fully prescribe the way the system is
22 managed. Other aspects of system regulation are more flexible, allowing for operational
23 flexibility and professional judgment, including releases for hydropower production,
24 irrigation and recreation. This decision space may be more or less available in any given
25 year depending on the system storage status and long term forecasts for water supply
26 (i.e. projected inflows into the mainstem river) for the coming year.

27 Each year the Corps’s Missouri River Basin Water Management Division (MRBWMD),
28 prepares an Annual Operating Plan (AOP) that presents pertinent information and
29 plans for regulation of the mainstem system under widely varying water input
30 conditions. The AOP examines a range of potential runoff scenarios that span 80
31 percent of the historical record. The draft AOP is circulated for public review by October
32 of each year. Public meetings are generally held in October and, after consideration of
33 Tribal and public comments, a final AOP is published in the December-January
34 timeframe. Spring public meetings are conducted to provide an update on the current
35 hydrologic conditions and projected System regulation for the remainder of the year as
36 it relates to implementing the Final AOP.

1 The studies included in the AOP provide an array of reservoir levels and releases that
2 may be expected under five runoff scenarios. The AOP describes the likely effects of the
3 five scenarios for the year ahead, and in doing so communicates the likelihood of
4 outcomes of interest to stakeholders. For example, the 2015-16 draft AOP indicated that
5 that for the 2016 water year the full flood control capacity of the reservoir system would
6 be available at the start of the runoff season, that the use of the Exclusive Flood Control
7 Zone was not anticipated under any of the five runoff scenarios covered in the AOP, and
8 that full service flow support under all runoff scenarios would be available to start the
9 navigation season.

10 Actual real-time regulation of the System is accomplished using the best information
11 and tools available and is adjusted to respond to changing conditions on the ground. As
12 the runoff season unfolds, there is a possibility that real-time regulation plans will
13 indicate runoff volumes, reservoir levels and releases outside those anticipated in the
14 AOP. Should that occur, the USACE will appreciably increase its communication and
15 outreach efforts to convey that information to stakeholders throughout the basin so that
16 other Federal, state and local agencies, Tribes, communities, and local residents can
17 take appropriate actions (USACE 2015).

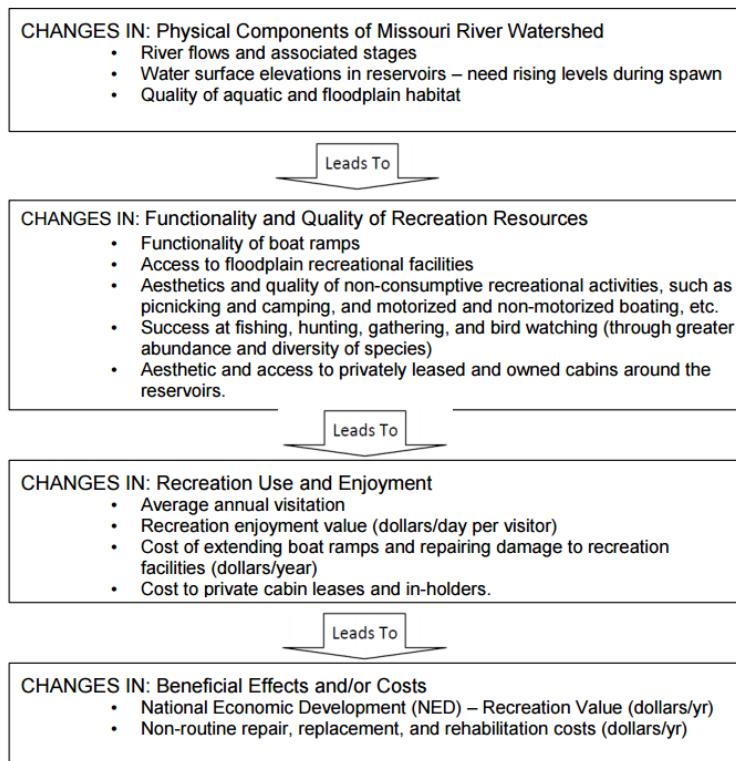

18 HCs were central to the development of the Master Manual, and therefore regulation of
19 the reservoir system in accordance with the manual allows the authorized purposes to
20 be served and the corresponding HCs to be considered. Real time operations are
21 adjusted on occasion to better serve specific project purposes or reduce impacts to HCs,
22 but these adjustments are made only after evaluating impacts to all authorized
23 purposes.

24 **5.2.3 Assessment of effects of actions under the MRRMP**

25 During the development of the MRRMP, long-term implications for HCs of a wide range
26 of alternatives were estimated using various tools and approaches and explored with
27 stakeholders over several rounds of engagement. This section reviews how this was
28 done as links can be made to proposals for using some of these techniques in future HC
29 analysis under an AM Plan.

30 In August 2014, MRRIC reached final consensus on “Human Considerations (HC)
31 Objectives and Performance Metrics” (MRRIC 2014) a 90- page report that detailed how
32 MRRIC would prefer to see potential impacts from alternatives on human
33 considerations expressed. HCs were broadly organized into the four primary accounts of
34 Environmental Quality (EQ), National Economic Development (NED), Regional
35 Economic Development (RED) and Other Social Effects (OSE). Within each account,
36 performance measures for various HCs were outlined, along with flow charts that

1 illustrated how changes in physical components of the system could lead to ultimate
 2 outcomes of concern expressed in performance measures. An example of one such flow
 3 chart, for recreation is shown in Figure 86 below.

4

5 Figure 86. Flow chart of inputs considered for recreation.

6 In this particular case, the ultimate performance measure for recreation is expressed in
 7 dollars per year. However, there are many analytical stages to arriving at this number,
 8 some of which require considerable time and resources to develop. In the preliminary
 9 stages of alternative review, other tools were therefore used to help communicate how
 10 alternatives might affect HC interests:

- 11 • Hydrology and Hydraulics Visualization - (H&H) modeling by the USACE resulted in
 12 daily stage and flow predictions for several thousand cross sections of the Missouri
 13 River mainstem for each alternative. Data were made available to stakeholders for a
 14 subset of locations through an interactive spreadsheet tool, HydroViz. With this tool
 15 and knowledge of critical flow and stage levels for any given HC, a qualitative
 16 comparative assessment of impacts on HCs could be made.
- 17 • Proxy measures - During all but the final round of alternative development, proxy
 18 measures were used to help compare the relative impacts of alternatives. Proxy
 19 measures were selected in collaboration with MRRIC from the upper end of the flow

chart diagrams. For example, in the case of recreation, proxies were developed that summarized how H&H differences would change the proxies (see DEIS Chapter 2 and Appendix A: Human Considerations Proxies and Round 1 and 2 Bird Alternative Proxy 2 Results for further discussion of this process).

Table 54. Sample proxy list for recreation.

Objective / Location	Proxy Metric	Units	Description	Directionality
Recreation/Reservoirs and River Reaches	Number of days with operable boat ramps	# of Days	Operable boat ramps are when stages and elevations fall between minimum and maximum normal boat ramp elevations	High
Recreation/River Below Gavins Point Dam	Number of chutes, backwaters, or shallow water habitat areas	#s	The number of chutes or number of shallow water habitat areas provide a proxy for recreation in terms of potential opportunities for recreational access, slower river water velocities, and safety.	High
Recreation/Three Upper Reservoirs	Number of days above the conservation pool elevation, the mid-2000s drought elevation, and an elevation between these elevations at upper three reservoirs	# of Days	Conservation pool elevations represent important elevations to support both access and fisheries health. Drought pool elevations from the mid-2000s represent important elevations to evaluate how severe drought affects access and fisheries health effects. The pool elevations between the conservation pool and drought elevations represent important elevations to evaluate alternatives.	High
Recreation/Three Upper Reservoirs	Normal to improved fishing success at three upper reservoirs	Yes/No	Fishing success is defined at upper three reservoirs through rising spring reservoir elevations	High (Number of yeses)

Because most proxies were readily derived from H&H modeling, they could be calculated and summarized within 2-3 weeks of the completion of H&H model runs. In this way, numerous iterations of alternatives could be examined. An important limitation of proxies, however, is that while they are helpful for comparing relative performance across alternatives, they may not provide information on the significance of impacts (e.g. how important is a 14-day reduction in number of days of summer boat ramp access?). Proxy measures were also left unweighted in terms of relative importance across locations, though supplementary information (e.g. # boat ramps per area) was provided where possible to help inform this consideration.

A summary of the proxies used in the development and screening of bird test alternatives are shown in Table 55.

1 Table 55: Summary of proxies used during the development of the MRRP

Resource Area	Proxies considered
Commercial Sand and Gravel	Average annual change in sediment accumulation rate at St. Joseph, Kansas City, and Hermann
Cultural Resources	Days and site-days of greater-than-normal erosion and/or exposure risk in reservoir and river reaches.
Fish and Wildlife	Change in Aquatic/Floodplain Habitat Classes along the mainstem Acres of wetland habitat classes along the mainstem Number of occurrences of flows below 9,000 cfs (thought to be associated with dewatering) in the Ft Randall to Lewis and Clark Lake reach
Flood Risk and Interior Drainage	Days of flood stage exceedance Days of flood stage +5' exceedance Interior drainage flapgate elevation exceedance
Hydropower	Annual seasonal generation (MWh) Seasonal generational value (\$) Seasonal maximum capacity (MW)
Irrigation	Number of days outside normal operating conditions during the irrigation season by county
Property Tax Base	Number of acres that would be acquired by the Federal Government, as an indicator of lost local tax revenue
Navigation	Number of days at or above full service Number of days above at least minimum service Season Length Service level at Sioux City, Omaha, Nebraska City and Kansas City
Recreation	Number of days of boat ramp operability by season Number of days that upper three reservoirs are at conservation pool, mid-elevation or minimum drought elevation (indicators of conservation and fisheries health) Number of years of "good" fishing success years
Thermal Power	Number of days that water intakes are inoperable Number of days that river temperatures exceed thresholds considered to be problematic
Wastewater	Number of days below low flow criteria
Water supply	Number of days outside normal and shutdown operating elevations for numerous municipal, commercial and industrial facilities

2

- 3 • Analysis of the MRRMP-EIS alternatives - Finally, the MRRMP-EIS alternatives
 4 were evaluated using the detailed analyses described in Chapter 3 of the Draft EIS
 5 and accompanying Human Considerations technical reports. The methods used to
 6 calculate National Economic Development (NED), Regional Economic Development

1 (RED), Environmental Quality (EQ) and Other Social Effects (OSE) measures
2 followed USACE guidance (Planning Guidance Notebook ER 1105-2-100).

3 These model results provided the best available estimates of how management actions
4 might affect HCs for *long term planning purposes*, and were vital in aiding
5 conversations about alternatives during the MRRMP-EIS review process. However,
6 precise predictions of how particular actions may affect specific HCs in any given year
7 cannot necessarily be made using these methods. The long-term planning analyses of
8 impacts to HCs from the MRRMP-EIS alternatives were based on H&H models that are
9 different from the operational models used by USACE to plan for the year ahead and to
10 operate the system on a daily and hourly basis.

11 **5.3 Plan and Design**

12 **5.3.1 Management actions considered in the MRRMP-EIS**

13 The EA identified and screened a range of management actions, including new
14 operations that might be undertaken to avoid jeopardizing the three Federally-protected
15 species. A subset of these actions was incorporated into the six alternatives evaluated in
16 the MRRMP-EIS. Some actions were included in all alternatives, while others were
17 included in only one of the six alternatives.

18 A preferred alternative has been identified for the Draft MRRMP-EIS. A selected
19 alternative will be identified in the Final EIS and a proposed action described for
20 Section 7 consultation with the USFWS. Following the consultation, a Record of
21 Decision (ROD) will determine which set of actions may be implemented in the AM
22 program. (This process is described in Section 2.2.5). Following the ROD and during
23 implementation of the MRRP, new information acquired about action effectiveness,
24 population dynamics, and system performance may lead to a determination that the
25 actions in the ROD are insufficient and that other actions should be evaluated for future
26 implementation.

27 This Draft AM Plan accompanies the Draft EIS and reflects the preferred alternative, but
28 retains the broader set of management actions and associated decision criteria
29 developed as part of the DEIS/AMP process. They are organized into three categories:

- 30 1) Category 1 - actions that have been evaluated in the DEIS and identified as part of
31 the Preferred Alternative;
- 32 2) Category 2 - actions evaluated in the DEIS but not identified as part of the
33 Preferred Alternative;
- 34 3) Category 3 - actions not evaluated in the DEIS.

1 Following the ROD, actions will be sorted in a similar fashion according to whether or
2 not they are included in the ROD and/or evaluated in the MRRMP-EIS. Actions in
3 category 1 following the ROD could be implemented at a programmatic level when
4 needed. Actions in categories 2 and 3 could not be implemented programmatically, but
5 may be explored further through research and pilot-scale implementation, as described
6 in Sections 3.2.4.2 and 3.2.4.3 for the birds and Section 4.2.4 for the fish. The
7 distinction between Categories 2 and 3 is significant because the processes that must be
8 followed to use actions not in the ROD will, in part, depend on whether and how the
9 action was evaluated in the EIS and if those analyses are still sufficient (See Section
10 2.2.5).

11 Management actions for birds fall into three general types: 1) those that create habitat
12 with construction or flows, 2) those that improve habitat quality or availability through
13 construction, modification, or flows, and 3) those that directly protect nests, chicks,
14 and/or adults to improve survival. Actions targeting bird populations or their habitats
15 identified in the Preferred Alternative include (see Section 3.2.4.1)

- 16 • In-channel habitat construction
17 • Flow management to avoid take
18 • Sandbar augmentation and modification
19 • Vegetation management
20 • Predation management
21 • Human restrictions measures

22 In addition to the above measures, actions evaluated as part of the EIS but not included
23 in the Preferred Alternative include (see Section 3.2.4.2).

- 24 • Habitat-forming flow releases (Spring and Fall)
25 • Lowered nesting season flows

26 For pallid sturgeon, actions identified in the Preferred Alternative include the following
27 (see Sections 4.2.5 and 4.2.6):

- 28 • Population augmentation
29 • Mechanical construction of IRC habitat
30 • Mechanical construction of spawning habitat
31 • Fish passage at Intake Dam on the Yellowstone River
32 • The potential for a test spring pulse flow aimed at synchronizing pallid sturgeon
33 spawning

- 1 Under the Preferred Alternative, efforts focused on the pallid sturgeon include the
2 scientific research described as Level 1 and 2 activities in Section 4.2.4 and detailed in
3 Appendix C.
- 4 Changes in flow regime for pallid sturgeon recruitment were the only actions evaluated
5 in the EIS but not included in the Preferred Alternative (except as a potential test
6 operation). (see Sections 4.2.5 and 4.2.6):
- 7 Several of the flow actions listed above and under consideration are outside the
8 boundaries set by the Master Manual at the time of analysis, and would require
9 revisions to be made to the Master Manual prior to implementation. Guidance on the
10 steps necessary for this to occur is provided in Attachment 5 of Appendix A and is
11 discussed in several sections in Chapter 2.

12 **5.3.2 How HCs are considered in site-specific planning and design of actions under
13 the preferred alternative**

- 14 Under the preferred alternative, the USACE will be implementing actions outlined in the
15 ROD as prescribed by the requirements set forth in the BiOp and the AMP. They will
16 operate from a five-year Work Plan, wherein activities in the current FY are generally in
17 implementation, and have already undergone significant programmatic and site-specific
18 planning and design. Management actions planned for the following year (FY+1) would
19 have undergone similar evaluation and have been budgeted by the USACE. Subject to
20 appropriations and some modification due to changed site conditions, these projects are
21 generally “shovel ready”. Note that significant new findings, decision criteria in the AM
22 Plan, or system conditions that prevent construction could, in addition to
23 appropriations, affect the implementation of those projects.
- 24 Generally speaking, the projects identified in out years (FY+ 3 and FY+4) will have been
25 identified in general scope, but will not have undergone significant site-specific planning
26 and design. Within the current year, the planning and design for specific projects is
27 usually focused on those slated for implementation in FY+2. Those projects will be the
28 focus of the Work Plan development process and, consequently, to planning and
29 analysis similar to the process used to evaluate alternatives under the MRRMP-EIS.
30 Alternative sites will be considered relative to Program objectives, targets, constraints
31 (budget, etc.) and impacts (including beneficial and adverse impacts to HCs). These will
32 be evaluated using the same tools and procedures employed for the MRRMP-EIS, except
33 that the tools may have been updated or otherwise improved through implementation,
34 monitoring, assessment and validation.

1 Under the programmatic EIS performed for the MRRMP, specific projects will be
2 subject to a more detailed and site-specific environmental assessment than was possible
3 when the programmatic EIS was conducted. The subsequent document is an
4 Environmental Assessment if the programmatic EIS addresses adequately the
5 environmental effects of the specific component. If the generic EIS does not address
6 appropriately these impacts, a supplemental EIS is required. That EIS is targeted on the
7 specific environmental impacts that were not fully discussed in the programmatic EIS.
8 Supplemental analysis may also be required where there are significant new
9 circumstances or significant new information relating to the proposed project or its
10 impacts.

11 The essential components of the above efforts are, for each project (or set of projects if
12 so treated), a discussion of the proposed action, its environmental impacts (including
13 impacts to HCs), reasonable alternatives to the proposed action and their consequences,
14 mitigation of adverse impacts and any irreversible commitments of resources. Once the
15 alternative combinations of projects (specific management actions at specific sites) have
16 been evaluated in the planning process and a tentatively selected plan identified, each
17 specific project is subject to the traditional USACE Preconstruction Engineering and
18 Design process. Cost estimates will be prepared, along with construction specifications,
19 operation and maintenance O&M requirements, AM standards and criteria, monitoring
20 plans, as warranted.

21 As projects are contemplated in out-years (FY+4 and FY+3), then considered in more
22 detail at the FY+2 stage (including site-specific analyses) as part of the Work Plan
23 development and budgeting process, and finally revised and refined (as needed) in
24 FY+1, there are ample opportunities for evaluation, re-evaluation and engagement
25 around possible HC effects. Additionally, monitoring and assessment of implemented
26 projects and validation of the models and tools used to support HC analyses provide
27 added opportunity to revisit plans based on new understanding of impacts (adverse and
28 beneficial) of categories of management action on HCs.

29 **5.3.3 How HCs are considered in planning and design of actions outside the preferred
30 alternative**

31 Chapter 3 of the DEIS describes the iterative process of how actions for Federally-
32 protected birds and fish were assembled into alternatives and assessed for both their
33 efficacy in meeting their primary objectives with respect to these species, but also for
34 their impacts on human considerations. Through these iterations, HCs were examined
35 in detail and efficient alternatives were identified. Further, after a detailed analysis was
36 completed on the Draft MRRMP-EIS alternatives, a subsequent analysis investigated
37 the specific circumstances that could potentially lead to the greatest negative impacts to

1 HCs from each alternative (see Section 5.7.4). Potential amendments to the formulation
2 of alternatives with actions outside the preferred alternative have been proposed and are
3 described in Section 5.8. Should any of these actions be reconsidered in future, the use
4 of these amendments may help further reduce avoidable impacts on human
5 considerations, though further analysis may be required.

6 Independently of the application of the impact reduction measures outlined above, any
7 reconsideration of actions outside the preferred alternative is likely to initiate a new
8 round of assessments similar to those described in Chapter 3 of the DEIS. Additionally,
9 measures not included in the EIS are subject to a full NEPA evaluation, and actions
10 previously considered may require a supplemental EIS if there are significant new
11 circumstances or significant new information relating to the proposed project or its
12 impacts (see Section 1.1.6).

13 **5.4 Implementing the MRRP**

14 Implementation schedules for pallid sturgeon actions are outlined in Section 4.3.1. No
15 comparable schedule exists for the bird actions; implementation needs will be driven by
16 the current population status and the current and projected availability of ESH, which
17 will change with system storage and releases. Budget availability, new information and
18 other factors add uncertainty to the implementation plans and schedules for
19 management actions, and the Work Plan will require ongoing updates.

20 The Work Plan is a rolling, five-year projection of the most current projection of
21 implementation plans and schedules. The Work Plan for the current year is typically
22 implemented as planned, but may deviate from the Work Plan developed during the
23 prior year's planning effort as a consequence of changed field conditions or budget, or
24 on the basis of new information. Such changes would require approval at the
25 appropriate level and include the necessary collaboration/coordination as outlined in
26 Chapter 2.

27 Plans for the following year are treated similarly, as the budget is generally set (subject
28 to appropriations), but has added flexibility over the current year's plans. Out-year plans
29 are mostly for strategic planning and budgeting purposes, but also provide stakeholders
30 an early indication of likely action implementation.

31 During the implementation step, species and HC metrics or proxies will be monitored
32 according to the requirements discussed in Section 5.5. Real-time monitoring of
33 conditions could reveal situations that could require adjustments to be made in
34 implementation.

1 In such a case, a decision needs to be made whether or not to continue with the existing
2 operations or to adjust in some way. These decisions, if they involve flow modifications,
3 would be communicated in the same manner in which all flow management actions are
4 communicated, with the MRBWMD in the lead for making those communications. For
5 changes to implemented projects not involving flows, the MRRP will utilize the
6 Program's website to communicate the changes.

7 **5.5 Monitoring for Human Considerations**

8 **5.5.1 Introduction**

9 This section discusses how the USACE currently monitors HC-related issues, and
10 discusses proposals for improvements as a result of implementing the MRRMP-EIS.
11 These proposals require further review and consultation with the HC Team and with the
12 agencies as part of the implementation of the AM Plan.

13 The HC impact analysis in chapter 3 of the DEIS estimates the national economic,
14 regional economic, environmental and other social effects that would be expected to
15 result from implementation of each of the MRRMP-EIS alternatives. This analysis has
16 influenced the identification of a preferred alternative in the DEIS and will ultimately
17 inform the final selected alternative for the plan.

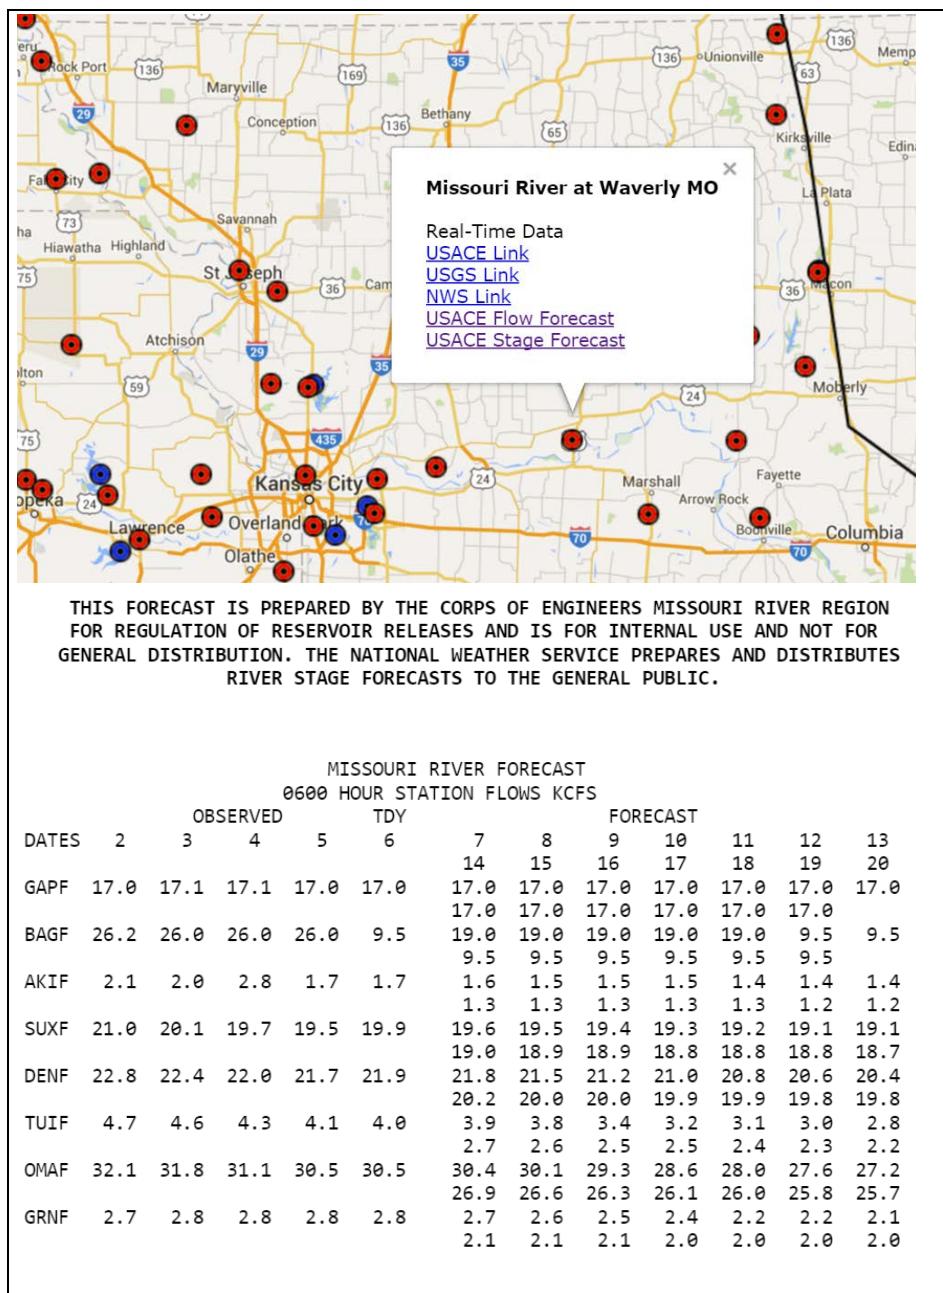

18 Inevitably, there are uncertainties in these estimates and, once implemented, decision
19 makers need to know if estimates are essentially accurate or prove to be misleading.
20 Further, in AM implementation of actions, accurate feedback on the predicted and
21 observed impacts to HCs can help improve the quality of information for ongoing and
22 future decision making.

23 For some HCs, sufficient information for decision making is probably already being
24 gathered and no further action is reasonably required; for others, it may not necessarily
25 be possible to know if predicted impacts on HCs are sufficiently accurate unless specific,
26 suitable information is systematically collected.

27 In this section, the uncertainties that exist in making estimates of impacts on HCs are
28 examined. An approach to determining which uncertainties are the most important to
29 resolve is discussed, and a preliminary prioritized list of candidate studies and actions to
30 do so is put forward for future discussion as part of the implementation of the plan

- 1 5.5.1.1 *How HCs are currently monitored (independent of the MRRP)*
- 2 The USACE Master Manual Chapter V describes the various data collection and
3 communication networks used to monitor the system. Other information is available
4 from other sources noted below. Some key points include:
- 5 • A wide range of data are collected on existing and anticipated hydrologic and
6 meteorological conditions (e.g. snowpack depths, evaporation rates, temperatures
7 etc), including real time automated reporting of hydrological and reservoir flow and
8 stage elevation data. This information is not only crucial for operating the system,
9 but is also helpful in understanding impacts on HCs, since most HC impacts are
10 directly correlated to river and reservoir flow and stage/elevation readings (over
11 various timescales).
- 12 • Much of this information is available to the public in real time today by the USACE
13 and USGS. For example, Hourly Data Collection Platform (DCP) data are available
14 online at: <http://www.nwd-mr.usace.army.mil/rcc/current.html>, while maps,
15 graphs, and tables describing real-time, recent, and past streamflow conditions for
16 USGS gages are available at: <http://waterwatch.usgs.gov/>
- 17 • The National Weather Service (NWS) also provides real-time and forecast data for
18 various points on the river. In this case, information is also provided on observed
19 historical flooding impacts associated with various stage levels (e.g.
20 <http://water.weather.gov/ahps2/hydrograph.php?wfo=fsd&gage=grws2>)
- 21 • Stage-discharge trends and rating curves at various locations throughout the system
22 are periodically updated by the USACE based on information from the USGS, as are
23 the hydrologic and hydraulic models that are calibrated with this information. These
24 tools and data can be used with stage-damage functions to estimate the effects of
25 flows on certain HCs.
- 26 • Other HC impacts are periodically examined and reported upon in various Technical
27 Reports issued by the USACE. For example, the flow requirements to meet
28 navigation targets were studied in 2000 (USACE 2000a).
- 29 • Major events, such as floods, are occasionally the subject of post-event investigations
30 that result in updated information on the effects of flows on HCs. For example, a
31 Post 2011 Flood Event Analysis of Missouri River Mainstem Flood Control Storage
32 (USACE 2012) examined how additional flood control storage could reduce flood
33 risk in the future and the impacts such a change might have on navigation, water
34 supply, hydropower, recreation, etc.
- 35 • USACE personnel make numerous reconnaissance trips to portions of the Missouri
36 River that are affected by project releases and of the reservoirs to obtain information
37 pertinent to System regulation. Effects of unusual release rates or reservoir levels
38 are also documented by field observations.

- 1 • Stakeholder concerns regarding HC impacts are gathered during the AOP
 2 stakeholder review process.
- 3 • MRBWMD routinely receive feedback (usually via phone calls) from the public on
 4 various issues when flows or elevations reach levels of concern.
 5

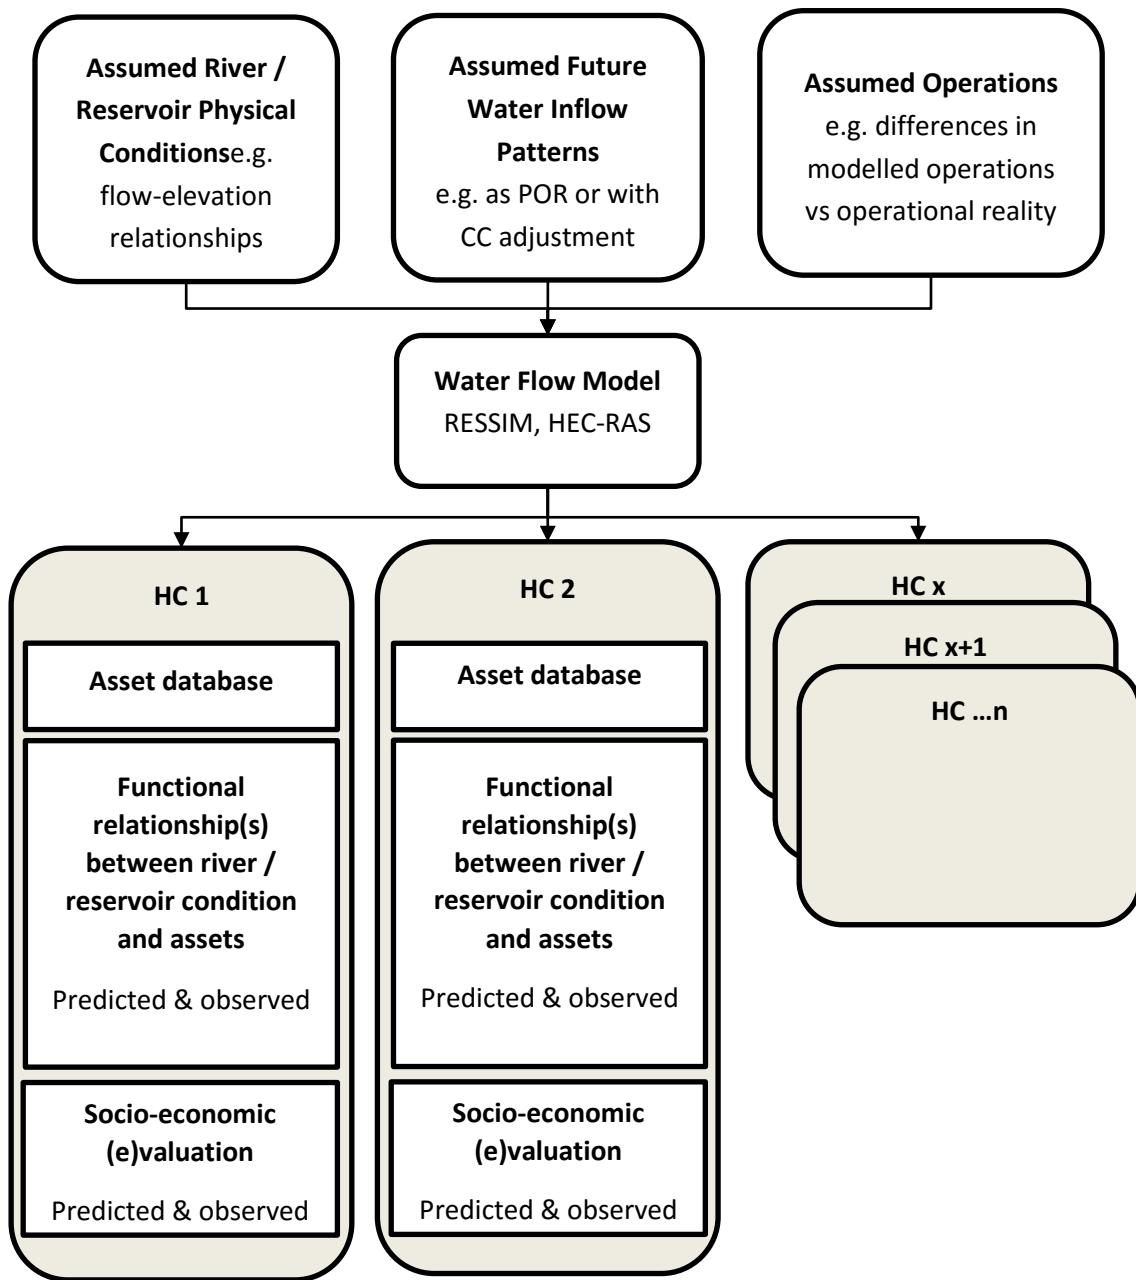

- 6 Figure 87. Example of real time online flow and stage observed and forecast information available today,
 7 Monitoring is also undertaken to assess the effects of projects implemented as part of
 8 the ongoing maintenance of the BSNP, related mitigation actions, projects undertaken

1 as part of the MRRP, and other flood risk management, navigation, and ecosystem
2 restoration initiatives. Although some of the specific monitoring requirements vary
3 depending on the project objectives, authority, and other factors, there are regular
4 monitoring efforts conducted in the lower Missouri River to track levee safety, and
5 responses in channel sedimentation and stability. These monitoring efforts are
6 conducted or overseen by the H&H Engineering staff from the Districts, and are used to
7 update models and assess effects to authorized purposes.

8 *5.5.1.2 Sources of Uncertainty in Predicting HC impacts*

9 The hydrological and HC modelling undertaken for the MRRMP-EIS was a
10 sophisticated undertaking. However, as with all models, it is important not to confuse
11 modelling (from which much can be learned) with reality. Examining sources of
12 uncertainty in modelling and considering their implications for management can help
13 consider the limitations of modelling predictions and also identify opportunities for
14 reducing some uncertainties in the future.

15 Figure 88 summarizes some of the main sources of uncertainty in estimating impacts of
16 management actions on HCs. Uncertainties concerning the top four boxes affect (to
17 some degree) not only each of the HCs, but the target species too. Their associated
18 uncertainties and implications are discussed in the model documentation (see
19 Fischenich et al. 2014) and were considered during the model review and certification
20 processes. Methods for reducing the uncertainties are described in the EA reports
21 (Fischenich et al. 2016) and are represented in the monitoring, analysis and model
22 validation needs for the species (see Chapters 3, 4 and appendices). Some
23 considerations specific to HCs (e.g. ice-jam flooding from ESH) described in this
24 chapter may include additional analyses associated with model uncertainties or
25 uncertain physical relationships.

2 Figure 88. Main sources of uncertainty in estimating impacts of alternatives on HC's

3 5.5.1.2.1 *Assumed river physical conditions*

4 The hydraulic modelling used to assess effects for the MRRMP-EIS employed a river
 5 channel geometry represented by surveys undertaken in 2012, with each alternative
 6 modified by a build-out of differing degrees and distributions of constructed pallid
 7 habitat (See DEIS Chapter 2 for details). Changes in channel morphology over time were
 8 not represented in the models. This was a reasonable assumption since the purpose was
 9 to examine the relative performance of management alternatives under identical

1 conditions, and the challenge of doing so against a changing backdrop of river
2 morphology would be unnecessarily complex. It is known, however, that sediment
3 aggradation and degradation is occurring along the river, and this issue is being
4 addressed by the USACE through ongoing monitoring and analysis as well as periodic
5 focused studies both external and internal to the MRRP. A further but related
6 uncertainty in the modeling for the MRRMP-EIS is that the actual location, size and
7 nature of habitat for the pallid sturgeon is not fully predictable at this time; those details
8 will evolve over time as the site-specific designs are formulated.

9 *5.5.1.2.2 Assumed future water inflow patterns*

10 For the purposes of the management plan, it was assumed that a reconstructed 82-year
11 period of historical inflows is representative of the flows and ambient conditions that
12 could be expected in future. Reconstructing this historical data set required its own
13 assumptions, and given the large range of natural variation in the Missouri River, the
14 previous 82 years may or may not be reasonably representative of the range of historical
15 variation. Moreover, the use of historical inflow data makes no accommodation directly
16 for potential changes in future inflows resulting from climate change. The hydrological
17 implications of climate change for this study is discussed further in the appendix
18 “Climate Change Assessment – Missouri River Basin” to the Hydrogeomorphic EA
19 (Fischenich et al. 2016).

20 *5.5.1.2.3 Assumed operations*

21 It is assumed that the operational rules for the various alternatives have been encoded
22 accurately and that they reasonably mirror how human operators would operate the
23 system under similar rules and conditions. This has been verified as part of the model
24 review and certification processes. However, this is again a simplification necessary for
25 modelling, and operators do often retain some flexibility to make real-time decisions
26 while still meeting rules. These real-time decisions are always more mindful of avoiding
27 unnecessary negative outcomes than are the algorithms embedded in the models, and
28 typically employ information or data not available to the models.

29 *5.5.1.2.4 Hydrologic and hydraulic model uncertainty*

30 It is assumed that the suite of RES-SIM and HEC-RAS models provide functionally
31 accurate representations of the hydrology, reservoir operations and hydraulics for the
32 System under the input conditions (discussed in Fischenich et al. 2016). These models
33 have been both calibrated and validated, and have undergone considerable internal and
34 external review. However, the models do not include all pertinent processes, and
35 consequently may deviate from actual conditions under some circumstances and over

1 time. Changes in channel conditions due to bank erosion or channel degradation, for
2 example, are not reflected in or simulated by these models and could affect resulting
3 river stages. A relative high degree of uncertainty exists in the ESH models, which
4 provide estimates of how much ESH can be expected in each reach due to sediments
5 forming sandbars and subsequently being eroded as a result of varying water flows in
6 the system (see Fischenich et al 2016).

7 Beyond uncertainties that are common to all flow-based changes to the system, for each
8 HC, there are typically uncertainties surrounding each of the following issues:

9 *5.5.1.2.5 Asset database uncertainty*

10 Most HCs involve the development and/or maintenance of one or more databases of
11 ‘things on the ground’ that are important to people and are potentially affected by
12 MRRMP-EIS alternatives. Uncertainties can arise when these databases are incomplete
13 or have misleading attributes (e.g. incorrect water intake shutdown elevations). It is not
14 always necessary to have a complete database in order for it to serve its purpose at a
15 programmatic level; for example, it is not necessary to account for every boat ramp or
16 every water intake, so long as the information contained is representative enough for
17 decision-making at this scale.

18 *5.5.1.2.6 Uncertainties in the predicted functional relationship(s) between river
19 and reservoir conditions and assets*

20 To predict how particular HCs might be affected by changes in habitat construction or
21 flow regimes, it is necessary to develop one or more functional relationships between
22 these changes and primary and sometimes secondary impacts on the interest. Primary
23 impacts are often those that were tracked using proxy metrics during the development
24 phase of the MRRMP-EIS process, and include examples such as hydropower
25 generation and days at various flood stages. Some HCs have very clear functional
26 relationships between flows and primary impacts (e.g. boat ramp accessibility), but
27 others are more complex and multi-staged (e.g. predicting how changes in flow regimes
28 and longer term storage differences might impact reservoir recreation visitation). Some
29 predictions would not necessarily benefit significantly from on the ground verification,
30 whilst others would.

31 *5.5.1.2.7 Uncertainties in socio-economic (e)valuation*

32 The final step in estimate impacts to HCs is to interpret how the changes in primary or
33 secondary impacts should be evaluated (or valued) in terms of its relative significance to
34 people locally, regionally or nationally. For the most part, USACE is adhering to

1 established models for doing so, and those models typically have the benefit of having
2 been tried and tested in a variety of contexts, nonetheless, they are not without
3 uncertainties. Sometimes these uncertainties could be reduced by comparing predicted
4 impacts with observed impacts, though in practice this too can be complex.

5 **5.5.2 Reducing uncertainties through monitoring**

6 While there are several sources of uncertainty in predicting impacts on HCs, not all
7 uncertainties matter for the purposes of planning, and some are more significant than
8 others for decision making.

9 Monitoring can be employed to help reduce uncertainties in a variety of contexts and
10 can be valuable for:

- 11 • Confirming that planned activities are undertaken properly (compliance monitoring)
12 • Passively observing actual impacts on the ground to provide data against which to
13 compare predictions or to watch out for possible unintended negative impacts
14 • As part of carefully crafted experiments to help test cause and effect hypotheses

15 Although some data can be obtained from third parties or with little or no incremental
16 effort to the program, other possible studies, while providing valuable information,
17 could compete for resources that might otherwise be used for other program priorities.
18 It is essential to have a structured and disciplined approach to identifying monitoring
19 proposals for HCs in this process.

20 The process of identifying and specifying monitoring needs for HCs, and the specific
21 identified studies introduced here should be not be considered definitive. Rather it
22 should be seen as a starting point for discussions. The intent is for the HC Team to
23 further consider the issues and provide recommendations for monitoring and analysis
24 needs under AM implementation of the MRRP.

25 *5.5.2.1 Selecting what to monitor – implementation and compliance monitoring*

26 In general, implementation and compliance monitoring typically has relatively little
27 scope for discretion for what could or should be undertaken. Some compliance
28 monitoring is legally required or prescribed by professional codes of practice, and
29 typically involves common-sense and low cost activities (e.g. good record keeping,
30 noting the conditions under which an action is implemented). Moreover, much
31 compliance monitoring is undertaken already by default (e.g. operational details such as
32 river flow rates and reservoir storage levels are continuously monitored already).

- 1 5.5.2.2 Selecting what to monitor - effectiveness monitoring
- 2 Some effectiveness monitoring also has a low cost, and some is also automatically
3 monitored (especially those with well-established hydrologic response curves, e.g. boat
4 ramp availability). Even in such cases, data needs to be analyzed to extract meaning,
5 and such data analysis requires resources.
- 6 However, effectiveness monitoring could easily consume large discretionary budgets
7 unless careful consideration is applied to the selection of which outcomes are most
8 valuable to monitor. Effectiveness monitoring provides useful background reference
9 information, but it does not necessarily provide or link up with other useful diagnostic
10 information that might ultimately be required to understand why the status and trend of
11 a particular outcome might be changing. A key consideration, therefore, is to ensure that
12 to the extent possible effectiveness monitoring is integrated with targeted studies
13 (discussed below).
- 14 Some considerations for determining which areas to focus on for effectiveness
15 monitoring may include:
- 16 Responsiveness to management actions. The MRRMP-EIS analysis indicated which
17 aspects of HCs, in which locations and under which seasons are most likely to be
18 affected by specific actions (e.g. spring or fall habitat creation releases). HC indicator
19 selection should focus first on those areas predicted by the analysis to be differentially
20 affected by the new operations.
- 21 Significance of potential impact being monitored. The MRRMP-EIS analysis also
22 revealed the potential magnitude of HC impacts. All else equal, HC indicators should
23 focus on high potential impact areas.
- 24 Representativeness to underlying concern. When selecting indicators, consideration
25 should be given to the relationship between the indicator and the underlying issue of
26 interest; the closer this relationship, the better. Care needs to be taken to identify non-
27 linear relationships between an indicator that can be measured and the underlying
28 interest.
- 29 Credibility and verifiability. It is important that decision makers and stakeholders have
30 access to accurate and credible information. Credibility may be imparted by various
31 characteristics of a situation, but is enhanced when readings can be checked (e.g.
32 through regular QC reviews) or are subject to spot auditing.

1 *Cost effectiveness of collection / interpretation.* All else being equal, the least cost way
2 of obtaining required information should be sought.

3 *Versatility.* Where a single measurement could act as an effective indicator for a wide
4 range of issues, it should be preferred.

5 *Timeliness for intended purpose.* Information is needed on different timescales. When
6 HC indicators are selected, thought should be given to the practicality of whether
7 information from each source could be made available in time for its intended use.

8 *Ability to simplify.* Because of the scale of the task at hand, it will be important to seek
9 out indicators that can be scaled back or simplified over time once the indicators map to
10 actual impacts.

11 *Engagement and partnership.* Information from various sources should be sought and
12 welcomed; however, all information should be subject to the credibility and verifiability
13 tests previously mentioned.

14 5.5.2.3 *Selecting what to monitor - targeted studies*

15 Targeted studies may be expected to require the most resources, but should also have
16 the potential to deliver the greatest benefit to decision makers. Features of
17 circumstances where targeted studies might be of highest value (and therefore have the
18 highest priority) may include:

- 19 • Where the MRRMP-EIS HC analysis has identified a potentially high value impact
20 associated with at least one alternative but where there is a large uncertainty as to
21 the probability and/or consequences of the hypothesized impact;
- 22 • Where the influence of this uncertainty is significant to understanding the overall
23 MRRMP-EIS HC analysis for a resource area;
- 24 • Where future management choices may be influenced by resolving or reducing the
25 uncertainty;
- 26 • Where there is a realistic and practical way of reducing the uncertainty, in a way that
27 could be expected to have sufficient statistical power or otherwise to provide
28 compelling weight of evidence within a reasonable timeline;
- 29 • Where there is a high ratio of the value to managers of the information anticipated to
30 be gained from the study relative to the cost (money, time etc) of acquiring the
31 information.

- 1 5.5.2.4 *Target study screening and prioritization questions*
- 2 The above considerations can be used to help screen and prioritize candidate target
3 studies under the MRRP AM Plan. The questions below are drawn from those
4 considerations and are provided as examples, cast in a relatively open-ended form. The
5 HC Team should revise these as needed to guide screening and prioritization activities.
- 6 *What is the key assumption / relationship / hypothesis needing analysis?* Summarize
7 the source of uncertainty in understanding or estimating the potential impacts of
8 alternatives on a resource area.
- 9 *How wrong or inaccurate could the base assumption be?* There are often limits to how
10 wrong an assumption could reasonably be. If being off by the maximum possible error is
11 unlikely to influence a decision, then the issue may not require further investigation.
12 Being wrong or inaccurate is not necessarily important; sometimes even an order of
13 magnitude of error in one assumption may not be of significance to an overall output.
- 14 *How frequently is the issue relevant?* The consequences of some uncertainties may be
15 felt continuously or every season or year. Some events, such as major floods, occur
16 rarely but may lead to significant impacts when they do occur. Other issues may require
17 an unlikely combination of factors to align before the assumption becomes relevant. In
18 cases where extremely large consequences could result, this may nevertheless be a valid
19 reason to investigate further. However, all else equal, priority should be given to those
20 issues that are likely to be relevant more often than not.
- 21 *How readily could new information resolve the issue or reduce the uncertainty?* Not all
22 uncertainties can readily be resolved or reduced through desktop or field studies. A
23 priority study would provide actionable information in a timely way.
- 24 *How conclusive could this new information be expected to be?* A major challenge on the
25 Missouri River will be to provide information that can help distinguish the signal of an
26 impact associated with a particular management action from the noise that results from
27 the large range of natural variation on the river. Care must be taken to ensure that the
28 information collected can ultimately be used to resolve the issue.
- 29 *What resources would be required to acquire this new information?* Outline the
30 approach to address the uncertainty and estimate (at first to an order of magnitude), the
31 cost of the investigation, including staff time and other resource requirements.

1 **What is the return on investment?** Aggregating the above, describe (or otherwise
2 estimate) the relative value of the new information that the study could yield relative to
3 the cost of acquiring it.

4 **5.5.3 Screening to identify higher priority monitoring studies.**

5 Uncertainties related to HCs that were identified during the MRRMP-EIS were screened
6 and prioritized to establish an initial set of monitoring and assessment needs. Included
7 were two basic sets of potential studies: 1) those associated with uncertainties
8 surrounding HC effects from mechanical habitat creation actions in the Preferred
9 Alternative, and 2) those associated with uncertainties from flow actions, including
10 possible test flows under the Preferred Alternative and other flows evaluated in the
11 DEIS that could be required to meet objectives at some future point.

12 This initial screening exercise was executed by the AM Team with input from the
13 technical specialists working on the EIS and that developed the EA. It is intended to
14 provide the HC Team with a starting point for their efforts and to provide the agencies
15 with an early estimate of monitoring needs and costs for planning and budgeting
16 purposes. It is understood that the HC Team will revisit and revise/refine this list using
17 more complete information and with broader input so that they can make sound
18 recommendations to the Management Team.

19 Drawing from the discussion of prioritization factors presented in Section 5.5.2, the AM
20 Team used the following considerations and approach to identify which of the
21 uncertainties are most significant to decision making and whether monitoring,
22 additional studies or other actions are warranted:

23 **Importance of an uncertainty:** The importance of an uncertainty is implied by:

- 24 • consideration of how large an uncertainty is suspected to be, including if and how it
25 interacts with other uncertainties (the greater the uncertainty or more likely it is to
26 combine with other uncertainties, potentially the more important)
27 • consideration of the magnitude of the adverse impacts from being wrong (the greater
28 the possible negative consequences associated with the uncertainty, the more
29 important)
30 • consideration of the significance to decision-making of reducing the uncertainty (i.e.
31 the more likely that resolution of the uncertainty could lead to different, senior
32 management-level decisions being made, the more important).

33

1 The candidate studies were graded on a 1 to 5 point scale for each of the three factors
 2 based on the judgment of analysts. Overall importance of reducing the uncertainty was
 3 calculated simply as the sum of the three sub-considerations.

4 **Effectiveness of a study to address the uncertainty:** Studies or other actions are
 5 expected to be effective if they can significantly reduce an uncertainty within the
 6 timeframe required for decision making under the MRRP. The ability to resolve the
 7 uncertainty efficiently weighs in favor of undertaking the study.

8 The relative effectiveness of the study in reducing the uncertainty was also rated on a 1
 9 to 5-point scale, where 1 indicates that the study would have a relatively low likelihood
 10 of reducing the uncertainty and a 5 indicates that the study would either remove or very
 11 significantly reduce the uncertainty.

12 **Cost of a study to address the uncertainty:** The cost of the study should consider
 13 the full range of resources required to undertake the study. The lower the cost of a study,
 14 the more resources remain available for other program needs and so the higher the
 15 priority. Costs for each study/activity were estimated at order-of-magnitude.

16 The overall value of a study is considered to be one that is both effective and that
 17 reduces an important uncertainty. For the purposes of this analysis, a score for overall
 18 study value is read off from the lookup table shown in Figure 89. It can take the range of
 19 1 to 10, where 10 indicates a highly effective study that resolves a very important
 20 uncertainty.

		Study Effectiveness at resolving or reducing the uncertainty				
		5	4	3	2	1
Overall importance of reducing the uncertainty	15	10	9	8	6	5
	13-14	9	9	7	6	5
	11-12	8	7	6	5	4
	9-10	6	6	5	4	3
	7-8	5	5	4	3	2
	4-6	4	4	3	2	1
	3	3	3	2	1	1

21
 22 Figure 89. Lookup table for calculating the overall value of a study.

23 Finally, after the cost for the study was approximated, the ratio of study value to cost
 24 gives a relative sense of the value of acquiring the information. A summary of these
 25 judgments is presented in Figure 90.

Potential HC Monitoring Studies and Screening

Concern (Expressed as an Hypothesis/Reason for Evaluation)	Relevant Interest Groups (P-Primary; S-Secondary)										Relative importance of addressing the concern	Ability to Resolve	Overall Study Value	Approx. Cost	Rel. Value of Info	Priority	
	Agriculture	Cultural Res.	Dredging	Flood Risk	Local Gov't	Navigation	Recreation	Thermal	Wastewater	Water Quality							
Sub-Concern (Expressed as an Hypothesis/Reason for Evaluation)											Potential actions to resolve or reduce the concern	Degree of Uncertainty Significance of Impacts	How well could the action reduce the uncertainty?	Using Lookup table in Chapter 5.	Overall Study Value / Cost	H-M-L	
Constructed Habitat (Preferred Alternative)																	
Constructed habitat can reduce conveyance and result in localized increases in stage that can induce flooding.	P	P	S	S							Predict, then monitor stages at habitat construction sites using a BAC design. IRC sites can be used to monitor and model conveyance effects.	3 5 4	12	4	7	400	0.02 M
Constructed ESH can induce ice jamming, resulting in localized and reachwise increases in stage and flooding.	S P	P	S	S S	S						Conduct a study of the effects of ESH on ice jam formation and try to identify critical thresholds.	3 4 4	11	3	6	250	0.02 M
(see above)											Monitor ice jam formation in conjunction with ESH implementation, using scaled implementation to help identify thresholds.	3 4 4	11	2	5	100	0.05 H
Constructed habitat can raise local water surfaces and, hence, local ground water levels, leading to interior drainage impacts.	P		P	S							Monitor ground and surface water levels at sites adjacent and immediately upstream of habitat construction sites to determine effects.	3 4 3	10	2	4	400	0.01 L
Constructed habitat can lead to changes in local flow patterns, inducing localized and systemic bank erosion, threatening infrastructure and land	P P	P	S S S	S P P	P						Monitor erosion at habitat construction sites using a BAC design.	3 3 4	10	4	6	300	0.02 M
Construction of ESH causes local erosion that exposes important cultural resources, state parks, historical properties, etc.	P	P	P	S								3 5 5	13	4	9	300	0.03 H
Constructed habitat can cause shifts in local/reachwise sediment dynamics, leading to localized bed level adjustments (scour and	P	S P	P S P	P	P						Monitor bed-elevation changes.	2 3 3	8	4	5	200	0.03 M
IRC construction can cause localized shoaling that affects performance of the BSNP.	S S S	P									Same as above	2 3 3	8	4	5	200	0.03 M

Navigation economic impact costs assumed in the DEIS are outdated and maybe under / overestimating impacts		P									Navigation shipping study (pilot, or full)	2 1 2	5	5	4	180	0.02 L
FRM database may be indicating false positive / negatives associated with various flow conditions	P										Flood Impact groundtruthing during test or naturally occurring high-flow periods	2 3 4	9	4	6	100	0.06 M

1

2 Figure 90.Preliminary prioritization of HC monitoring studies

1 The candidate HC monitoring studies outlined in this chapter represent only a small
2 number of the studies that could be considered. If the purpose were to precisely account
3 for all potential HC impacts of the Management Plan, a larger number of studies may
4 have been evaluated. However, the studies put forward are candidates proposed by the
5 AM Team and analysts involved in the EIS as providing good potential value in
6 improving the status of information for decision making and a reasonable starting point
7 for the Program to consider.

8 Even so, the combined cost of the studies presented here represents a significant
9 investment and it is not clear that the Program has a responsibility to fund them or that
10 resources for these studies should be diverted from other uses (e.g. project
11 implementation for species benefits). For these reasons, the monitoring studies are
12 presented here with a relative priority from a HC value of information perspective for
13 decision makers to consider, but without comparison to other Program investments.

14 It is expected that the uncertainties that might be addressed and their rankings
15 according to the above factors might well change over time, so it is important that these
16 be reconsidered from time to time. It is envisioned that the HC Team will do just that as
17 a central part of their charge.

18 **5.5.4 Monitoring of HCs under the MRRP Preferred Alternative**

19 Based on the screening discussed in the previous section, a handful of potential focused
20 studies and monitoring/assessment actions were identified for actions included in the
21 Preferred Alternative of the DEIS. The following sections briefly outline the concern and
22 the scope of the proposed studies. Study scopes and/or monitoring and assessment
23 protocols are presented in Appendix H.

24 Stakeholders have articulated concerns that ESH and IRC habitat projects could have
25 negative consequences for human considerations, including socio-economic benefits
26 and cultural resources. Most of these concerns are related to perceptions that habitat
27 projects may negatively affect flood stages, groundwater levels, ice jams, or channel
28 conditions (erosion or deposition) and would subsequently impact interests (e.g.
29 navigation or water intakes). At the same time, it is possible that ESH and IRC projects
30 could have positive socio-economic benefits, by increasing the capacity of the channel to
31 convey floodwater and providing recreational benefits, for example. Hence, investment
32 in monitoring of outcomes from ESH and IRC projects as they relate to HCs may be
33 warranted.

34 Assessment of effects of ESH and IRC on human considerations generally requires data
35 collection sufficient to address cause and effect; e.g. is flooding or bank erosion or

1 shoaling the result of the project or the result of background variation of the river? This
2 question can be challenging to answer in a highly dynamic river system. There are three
3 potential approaches to establishing an assessment of cause and effect:

- 4 • **Before/after monitoring.** Before/after monitoring seeks to establish
5 processes and rates at a site before manipulation and after manipulation so the
6 amount of change can be associated with the manipulation. The before/after
7 approach is frequently limited by the ability to monitor the before condition
8 sufficiently to establish baseline conditions. In a river system characterized by
9 high inter-annual to inter-decadal variability establishment of sufficient of
10 baseline conditions may require many years of monitoring. Pre-existing data may
11 be useful in some cases, but data that were not collected specifically for the
12 monitoring question at hand are frequently poorly focused.
- 13 • **Control/impact monitoring.** In control/impact monitoring a manipulated
14 site is match to a non-manipulated (control site) and differential change is taken
15 as the result of the manipulation. The challenge in control/impact designs is
16 establishing that sites are sufficiently comparable.

17 Before/after and control/impact designs are frequently combined in so-called
18 BACI designs. The “staircase” design for IRCs (chapter 4) is a type of BACI
19 design that takes into account time-varying construction of IRC sites. The ability
20 of a BACI or staircase design to capture changes in a way that can be used to infer
21 cause and effect is also dependent on length of baseline (before) monitoring and
22 comparability of control and impact sites.

- 23 • **Computational modeling.** The third general approach is to use computational
24 modeling of sites, with and without manipulation, to assess sensitivity of human
25 considerations to the ESH or IRC project. The utility of a modeling approach
26 depends on the reliability of the type of model being used. For example,
27 computational hydraulic models comparing pre- and post-IRC construction
28 water surface elevations may be considered sufficiently reliable to evaluate effects
29 of construction on conveyance. On the other hand, models to predict bank
30 erosion or ice-jam effects may not be considered sufficiently reliable to evaluate
31 the effects on human considerations.

32 Variations or combinations of these three general approaches will likely be necessary to
33 provide useful assessments within budget and time constraints.

1 Another consideration in these assessments is the value of quantitative data compared
2 to qualitative or semi-quantitative data. Evaluations may benefit from a phased
3 approach in which qualitative data are used to establish whether a process is important
4 (for example, do aerial photographic surveys indicate new patterns of flow after
5 construction of ESH?) followed, if needed, by a quantitative assessment of how much, if
6 any, bank erosion is caused by the new flow patterns.

7 Note that the proposed studies outlined below and in the appendix will be updated as
8 the WP for the MRRP is formulated. The descriptions, scopes and protocols presented in
9 this AM Plan should be regularly updated to reflect current and proposed studies based
10 on the approved WP.

11 With respect to potential impacts on Tribal cultural sites, NHPA Section 106 and 110
12 will be followed as management plan actions are implemented based on NHPA
13 Programmatic Agreements and consultations.

14 5.5.4.1 *Monitoring to address flooding concerns associated with constructed Interception*
15 *and Rearing Complexes (IRCs)*

16 Concerns were raised by stakeholders during the MRRMP's development that
17 constructed IRC habitat can reduce conveyance and result in localized increases in stage
18 with subsequent flooding. Model studies show the magnitude of effects are small (within
19 measurement error) and actually decrease stages for most flows, and model results are
20 supported by basic hydraulic principles. The significance of this concern is high and the
21 value of information (VOI) is high because the results of the proposed study should
22 dispel pervasive concerns and may document stage reductions, nor increases, associated
23 with the proposed IRCs.

24 The proposed study involves the application of the USACE HEC-RAS models to study
25 reaches where IRCs are to be implemented and then monitoring actual stages in those
26 reaches using a Before-After-Control (BAC) study design. Comparisons between
27 predicted and monitored stages can be used to either a) validate the models, or b)
28 recalibrate and then validate the updated models. The IRC sites identified as part of the
29 experimental design for pallid sturgeon (see Section 4.2.6.3) can be used to model and
30 monitor conveyance effects, and the monitoring proposed for the IRC study (see
31 Appendix E) can be adjusted slightly to accommodate the needs for the HC study.

32 Water surface elevations in reaches with IRCs as well as in control reaches will be
33 surveyed using either Lidar or conventional hydrographic survey equipment and real-
34 time kinematic global positioning systems (RTK GPS) or differential global positioning
35 systems (DGPS). Transect spacing will depend upon the particular site and should

1 provide sufficient spatial coverage for creating continuous surface maps of depth,
2 elevation, and velocity given the expected amount of spatial variation due to site specific
3 features as well as variation expected under variable discharges. Repeat surveys will be
4 conducted at each site utilizing the same transect design for subsequent surveys.
5 Appendix E illustrates an example reach with transects spaced at 20-m intervals
6 perpendicular along the recommended sailing line. Additional longitudinal survey lines
7 along the banks and in the thalweg may be used to improve accuracy of continuous
8 surface maps. The frequency and timing of surveys will largely depend upon flow and
9 water levels. At a minimum, one survey per site per year will take place, but additional
10 surveys will be scheduled as needed in order to obtain data for a sufficient range of flows
11 to develop rating curves and evaluate/validate the hydraulic models.

12 Details for the proposed study are provided in Appendix H.

13 5.5.4.2 *Monitoring to address localized sedimentation concerns associated with*
14 *constructed Interception and Rearing Complexes (IRCs)*

15 The concern here is that geomorphic adjustments in and adjacent to IRCs could result in
16 localized scour or deposition, resulting in human consideration effects like bank erosion,
17 scour near river infrastructure, or deposition in the navigation channel. The staircase
18 statistical design for assessing IRC habitat changes is well suited for addressing these
19 questions, although the frequency and extent of channel resurveys may need to be
20 increased for the human considerations.

21 The IRC staircase evaluation design includes complete topobathymetric surveys in
22 treatment and control reaches. These surveys will be used to construct hydrodynamic
23 models for evaluating the extent and temporal persistence of habitat types and for
24 evaluating transport from the navigation channel to the IRC. We expect that the channel
25 configuration at an IRC site will continue to evolve and adjust through some time period
26 post construction, and that the newly constructed IRC may also have a dynamic erosion
27 and deposition regime that differs from control sites. For this reason, the IRC reaches
28 will need to be periodically resurveyed to update the models. These resurveys can also
29 be used to assess the human considerations, in particular if, where, and how much
30 erosion and deposition occurs over time. To address human consideration concerns, the
31 spatial scope of the surveys may need to be increased somewhat upstream and
32 downstream to evaluate all potential effects. Resurveys for IRC habitats would be
33 annual or biennial right after survey and then increase in years between surveys as time
34 progresses. For the case of erosion or deposition that may relate to specific socio-
35 economic concerns, some complementary within-year resurvey may also be advisable.

36 Details for the proposed study are provided in Appendix H.

- 1 5.5.4.3 *Monitoring to address flooding concerns associated with constructed Emergent*
2 *Sandbar Habitat (ESH)*
- 3 Concerns were raised by stakeholders during the MRRMP that constructed ESH habitat
4 can reduce conveyance and result in localized increases in stage with subsequent
5 flooding. Model studies show the magnitude of effects are small (within measurement
6 error) for the size and spacing of sandbars as historically implemented under the MRRP,
7 and actually decrease stages for most flows, and model results are supported by basic
8 hydraulic principles demonstrate that ESH has the potential to cause measurable
9 localized increases in water surface elevation. The significance of this concern is high
10 and the value of information (VOI) is high because the results of the proposed study can
11 be used to develop guidelines for the siting and design of ESH so as to avoid or minimize
12 the effects of water surface elevations.
- 13 The proposed study involves the application of the USACE HEC-RAS models to study
14 reaches where ESH is to be implemented and then monitoring actual stages in those
15 reaches using a Before-After-Control (BAC) study design. Comparisons between
16 predicted and monitored stages can be used to a) validate or recalibrate and update the
17 models, b) develop general criteria for planning and design of ESH, and c) refine designs
18 for individual ESH projects.
- 19 Water surface elevations in reaches with ESH as well as in control reaches will be
20 surveyed using either Lidar or conventional hydrographic survey equipment and real-
21 time kinematic global positioning systems (RTK GPS) or differential global positioning
22 systems (DGPS). Transect spacing will depend upon the particular site and should
23 provide sufficient spatial coverage for creating continuous surface maps of depth,
24 elevation, and velocity given the expected amount of spatial variation due to site specific
25 features as well as variation expected under variable discharges.
- 26 Repeat surveys will be conducted in each study reach utilizing the same transect design
27 for subsequent surveys. Additional longitudinal survey lines along the banks and in the
28 thalweg may be used to improve accuracy of continuous surface maps. The frequency
29 and timing of surveys will largely depend upon flow and water levels. At a minimum,
30 one survey per site per year will take place, but additional surveys will be scheduled as
31 needed in order to obtain data for a sufficient range of flows to develop rating curves
32 and evaluate/validate the hydraulic models.
- 33 Details for the proposed study are provided in Appendix H.
- 34 5.5.4.4 *Monitoring to address potential ice-jamming and related flooding concerns*

1 associated with constructed *Emergent Sandbar Habitat (ESH)*
2 Sandbars have been identified as a possible contributor to ice jamming on some rivers,
3 resulting in localized and reach-wise increases in stage and flooding. Ice-jam floods are
4 common on the upper Missouri River, and the potential for localized flooding
5 downstream of Garrison Dam is of particular concern. Predicting the effects of ESH
6 construction on flooding potential, if any, will require a greater understanding of the
7 causes and effects of ice jams in the reach. Ice jams can cause considerable channel
8 scouring, avulsion, remove vegetation in the riparian zone, and affect the morphology of
9 sandbars upstream from the jam, within the jam, and downstream from the jam when it
10 breaks up and releases a pulse of water (Ettema and Daly, 2004).

11 This topic has received comparatively little study, and separating the effects of ESH
12 construction from other geomorphological processes in the reach may be a challenge.
13 Two potential studies were identified as part of the initial screening of HC monitoring
14 for the MRRP. The first study involves mining of historic ice formation records and
15 associated ESH conditions to try and obtain a useful relationship. The second study
16 involves real-time monitoring of ice conditions and water surface elevations in reaches
17 with and without ESH over time so as to obtain data useful for simulating ice jamming
18 and flooding in the reach. It may be difficult to run a controlled experiment given the
19 high natural variability of ice formation in the reach. Nevertheless, the study could use
20 the considerable real-time data already collected in the reach along with other
21 technologies such as Lidar, satellite-based remote sensing, and digital field camera
22 deployments to develop high benefit/cost datasets with strong cause/effect value.

23 Additional detail for the proposed studies will be developed by the Technical Team,
24 coordinated with the HC Team, and incorporated into Appendix H. The significance of
25 this concern is high and the value of information (VOI) is high because the results of the
26 proposed studies can be used to develop guidelines for the siting and design of ESH so
27 as to avoid or minimize the potential for ice jam formation and the effects of related
28 jams on local flooding.

29 *5.5.4.5 Monitoring to address localized erosion concerns associated with constructed*
30 *Emergent Sandbar Habitat (ESH)*

31 Constructed ESH can cause changes in local flow patterns, potentially inducing localized
32 and systemic bank erosion. This can be a significant concern, particularly where cultural
33 resources or infrastructure are threatened or where private land loss may occur. Erosion
34 is a natural phenomenon that is both common and widespread. However, accelerated
35 erosion can occur where ESH severely restricts channel conveyance or causes localized
36 hydraulic conditions conducive to bank scour.

- 1 The proposed study involves the monitoring and study of reaches where ESH is to be
2 implemented using a Before-After-Control (BAC) study design to assess bank erosion
3 frequency and magnitude and the impacts of any observed erosion. Comparisons
4 between project and control reaches as well as before and after comparisons of project
5 reaches may yield important information that could lead to the development of general
6 criteria for planning and design of ESH and help refine individual ESH projects through
7 AM. Bank erosion is difficult to accurately predict using numerical models particularly
8 where the erosion processes are highly stochastic, such as on unrevetted portions of the
9 Missouri River.
- 10 Topographic and bathymetric surveys will be conducted in reaches with ESH as well as
11 in control reaches using either Lidar or conventional hydrographic survey equipment
12 and real-time kinematic global positioning systems (RTK GPS) or differential global
13 positioning systems (DGPS). Transect spacing will depend upon the particular site and
14 should provide sufficient spatial coverage for creating continuous surface maps of
15 bankline position, elevation, and vegetation coverage given the expected amount of
16 spatial variation due to site specific features as well as variation expected under variable
17 discharges.
- 18 Repeat surveys will be conducted in each study reach utilizing the same transect design
19 for subsequent surveys. Additional longitudinal survey lines along the banks and on the
20 perimeter of ESH may be used to improve accuracy of continuous surface maps. The
21 frequency and timing of surveys will largely depend upon flow and water levels. At a
22 minimum, one survey per site per year will take place, but additional surveys will be
23 scheduled as needed in order to obtain data demonstrating the response of bank erosion
24 to particular conditions.
- 25 Details for the proposed study are provided in Appendix H.
- 26 5.5.4.6 *Monitoring associated with test flows*
- 27 The Preferred Alternative includes a provision for a Level 2 in-river spawning cue
28 release test. If included in the Record of Decision (ROD), the test flow would consist of a
29 one-time release from the System after year 8 if Level 1 studies do not provide a clear
30 answer on whether a spawning cue is important. This flow was one of several evaluated
31 in the DEIS. The impacts of this flow were analyzed under Alternative 6 of the DEIS.
32 The Level 1 studies will include monitoring naturally occurring high flows to gage
33 species response. The Level 2 test will include extensive monitoring to show the effects,
34 if any, on the species, if Level 1 studies are insufficient in determining species response.

1 A detailed design for HC monitoring for this test flow has not been undertaken because
2 to do will require additional information than is currently available. USACE and the HC
3 Team will consider a monitoring regime associated with such a test flow if it is required
4 and when the specifications for such a flow become clearer.

5 *5.5.4.7 Other studies and opportunistic monitoring under the Preferred Alternative*

6 Changes to channel configurations that increase habitat values for piping plovers and
7 pallid sturgeon also have the potential to increase attractiveness of the river for
8 recreational users. As a result, socio-economic benefits may also accrue in habitat
9 rehabilitation projects. This is due to the attractiveness of increased channel complexity,
10 increased sandbar availability, and generally increased habitat diversity in IRC and ESH
11 projects. Sandbars (as ESH or in IRCs) are especially valued by recreational river users
12 as campsite and picnic destinations where appropriate. Increased channel complexity
13 around ESH and IRC projects are also likely to increase habitat values and sportfish
14 production. These benefits may be substantial: over a one-year time inter al in 2004,
15 recreational use of the Lower Missouri River was calculated to be worth \$20.1 million to
16 \$38.7 million (Sheriff and others, 2011). Hence, recreational use may be worth assessing
17 to allow a complete and accurate evaluation of tradeoffs.

18 Assessment of recreational use would likely make use of the BACI or staircase design,
19 comparing recreational usage in control and treatment reaches. A useful metric would
20 be simply number of visits and this can be effectively determined using remote, time-
21 lapsed photography. Simple analysis of the photographic dataset could entail relative
22 numbers of visitors whereas more complex analysis could classify type of visit and relate
23 to economic impacts.

24 It may be possible to consider opportunistic monitoring of high priority HC issues
25 associated with the Level 1 pallid sturgeon natural flow events that could yield
26 information on spawning cue flow requirements. This is a discussion that could be
27 initiated between the HC and Fish Teams at an early opportunity.

28 **5.5.5 Monitoring considerations for potential future management actions**

29 As DEIS Chapter 3 shows, the largest potential for negative impacts to human
30 considerations come from the use of flow modifications. As discussed in Chapter 2, the
31 preferred alternative may not be sufficient to meet the objectives of the MRRP, and it
32 might be necessary to consider other alternatives, including actions involving flow
33 modifications. These may include those actions evaluated in the MRRMP-EIS or other,
34 as yet undefined actions that would be dictated by the science and understanding
35 developed through the AM Program.

1 Given this, it is prudent to consider the kinds of monitoring for human considerations
2 that might be necessary in such a case. In this section, three situations are considered:

- 3 1. Monitoring of HC issues that could be undertaken now in order to create better
4 baseline data against which to understand the impact of potential future flow
5 modifications,
6 2. Monitoring of HC issues that could be undertaken and completed before a flow
7 modification action is taken, and
8 3. Monitoring of HC issues that could be only undertaken in the event of a flow
9 modification.

10
11 In all cases, consideration should be given to the fact that channel changes are a
12 consistent feature of the river and the relevance of monitoring results over time should
13 be a factor considered in monitoring activity design and use.

14 5.5.5.1 *Monitoring of HC issues that could be undertaken now in order to create better*
15 *baseline data against which to understand the impact of potential future flow modifications*

16 This section describes a range of activities that could be undertaken soon after the
17 implementation of the AM Plan is initiated to help better prepare for a potential future
18 circumstance when a flow modification could be required. These activities are thought
19 to have relatively low cost (confirmation of this would be required) and would have a
20 range of benefits.

21 The primary purpose of these activities is to reduce uncertainties about how operations
22 (current and potential future) affect HCs and to organize or systematize the collection of
23 decision-relevant baseline information. The proposals listed here would help confirm or
24 refute predictions on which areas would or would not be affected by potential changes to
25 flow releases and would serve to focus attention on them if and when required. It could
26 help MRBWMD in its daily operational choices and would help economists and analysts
27 develop more complete and reliable correlations between historical data and impacts.

28 Secondary benefits of these activities would be to help improve the relationships and
29 communication pathways between Tribes, stakeholders and the USACE regarding the
30 links between flow changes and impacts on HCs, both now and under potential future
31 scenarios. In the early years of the AM Plan, it would encourage regular structured
32 conversations between the USACE and the HC Team regarding the details of how flow
33 choices affect interests. Doing so would help identify key indicators and methodologies
34 that could be referred to in actual planning situations should flow releases be used at
35 some time in the future. This would help build a shared sense of understanding on
36 specific issues that may currently be unclear for any party.

1 The following are preliminary suggestions that could be further discussed and developed
2 by the HC Team, in collaboration with the USACE.

3 **Create an online information clearing house for HC data**

4 As discussed above, there is currently no systematic collection or organization of
5 information regarding the impact of system operations on HCs. Information technology
6 advances in the past decade have made doing so a reasonable proposition. The data
7 collected could come from various sources and relate to different aspects of the impact
8 pathways between USACE operations and impacts to HCs. At the present time, the
9 USACE is not committed to undertaking or facilitating this kind of data management
10 due to the formidable challenges such compilation would entail; however, it can
11 appreciate the potential added value such information could have on AM planning.

12 For discussion purposes, examples of data that could be collected and made accessible
13 in a central location could include:

- 14 ○ Current and historical weather, snowpack levels, inflow, river stage, system
15 storage, reservoir elevation etc. (much of which, as previously discussed, is
16 already available online in various places)
- 17 ○ Automated data transfers of information currently being collected by
18 stakeholders (e.g. water temperature measurements, water quality
19 measurements, hydroelectric generation data, navigational craft data etc.)
- 20 ○ Information submission forms and data upload interfaces that enable the public
21 to send the USACE information relevant to ways in which system operations
22 might affect them (or perceive to affect them). For example, data on recreation
23 user data might be sought and collected on a regular basis; information on flood
24 damages associated with particular circumstances could be quickly shared;
25 information on irrigation problems or water supply intake issues could be
26 photographed and the details uploaded and logged etc.

27 Not all information gathered in this way would be actionable by the USACE, or
28 necessarily relevant to decision making due to compounding issues such as the need to
29 establish the veracity and accuracy of data submitted by outside parties. However, it
30 would provide for information exchange upon which discussions could be had with the
31 HC Team. All such data collection would need to be subject to similar (and strict)
32 provisions for ensuring high information quality. This is discussed further in Chapter 6.

33 The EIS uses the best currently-available information. Future decision making could be
34 even better informed through actions taken in the coming years to reduce decision-

1 relevant uncertainties where possible. The following paragraphs summarize initial
2 considerations for HC monitoring priorities by resource area. Not all resource areas are
3 covered at this time, but future HC Team discussions could develop these ideas in a
4 similar fashion.

5 **Recreation**

6 Overall, recreation impacts can be mostly inferred from factors that are already being
7 monitored – the location of constructed habitat, and changes in river stage and reservoir
8 elevations, fishing success, and fishery health. During the development of the MRRMP-
9 EIS, substantial effort was dedicated to updating and refining USACE's database of
10 recreation resources, including boat ramps, residency of visitors, types of visitors, etc.

11 The greatest information need, however, appears to be the need to confirm the assumed
12 relationship between system operations and various types of visitation. From the
13 statistical regressions on the lakes conducted by the project team, visitation at the lakes
14 was most influenced by summer lake elevations. A better understanding of how anglers
15 and other types of visitors respond to lake elevations and fishing pressure would further
16 refine the impact from system operations on lake visitation. Some of this information is
17 currently being collected by various state agencies although data collection is not
18 consistent across lakes and is not collected every year in most cases. Predictions of
19 visitation could be improved through the use of visitor surveys that seek to clarify what
20 features of the recreational experience most strongly influence visitation choices. For
21 example, in the case of an angler, how important is fishing success relative to reservoir
22 elevation in determining visitation choices?

23 Visitor use surveys in the river reaches could also improve precision around day use
24 value, since there remains some uncertainty about some activities (e.g., paddleboard
25 activities) and whether these visitors prefer low flows or high flows and is there a
26 threshold that would be important to consider in a decision to visit the area? Some of
27 this information is being collected by state Fish and Game visitor and creel surveys but
28 could be expanded to better understand how river flows affect various types of
29 recreation activities on the river.

30 When calculating regional economic impacts, more precise information on the relative
31 proportion of local versus non-local visitors would help better estimate how much
32 money is being spent by whom and whether the source of the expenditure is local or
33 from outside the region. Some states are again collecting this information as part of
34 their visitor and creel surveys.

1 The USACE could therefore engage with states to examine what information is being
2 collected and consider which, if any, data gaps for the purposes of this program are not
3 being collected. If valuable information is being missed, USACE could consider co-
4 funding state data collection based on a value of information evaluation. For example, it
5 would be useful to know whether building mechanical habitat for pallid sturgeon or
6 plovers increases or decreases recreation values.

7 **Irrigation**

8 Although the project team is confident in predictions of impacts of system operations on
9 irrigation intakes, some uncertainties remain that could be addressed at relatively little
10 cost. For example, it is assumed that if the river or reservoir level falls below a certain
11 intake operating threshold, as established and reported by the operator of that irrigation
12 intake, the intake will lose access to water for a full day. This may not be true and the
13 current irrigation evaluation could over-estimate negative impacts to irrigation (for
14 example, many of the intakes are portable and may be able to access water below critical
15 thresholds by moving the intake).

16 There is imperfect information on the technological and operational responses open to
17 irrigators at the various locations. For example, the model evaluates one likely response
18 of irrigation intake users to adverse conditions (river stages and reservoir elevations
19 falling below intake operating elevations), namely, a change in crop production. While it
20 is reasonable that irrigation intake users might consider a range of other responses (e.g.,
21 switching to a groundwater source, incurring costs to move the intake to the water,
22 growing a different mix of crops, or selling the land), this model is unable to evaluate
23 these alternative responses. Also, the extent of use of portable intakes is not fully
24 understood.

25 Further, as a result of inadequate data, the irrigation economic model does not capture
26 changes in cost to irrigators as a result of changing river/reservoir conditions.
27 Interviews with numerous intake owners, operators, and service providers failed to
28 uncover data or information that could be used to build a consistent cost profile for
29 irrigation intake owners and operators when they experience adverse river or reservoir
30 conditions. Consequently, it is assumed that production costs, as reported in crop
31 enterprise budgets, remain constant for a wide variety of irrigation conditions.

32 A survey of irrigation operators could gather further information on the following
33 issues:

- 1 • Further refine the current database of intake operators, improve the accuracy of
2 critical intake and operational thresholds;
- 3 • Further refine the cost response to these issues: how do costs actually change with
4 changes in water flows in the river. For example, what is the relative cost of moving
5 intakes versus other potential responses (reduced crop yields)? Clarify which
6 operators have access to alternative sources of water, and at what point these other
7 sources of water would not be available;
- 8 • Improve the understanding of how yield varies by water loss. The model currently
9 assumes a linear relationship between yield and access to water through intakes up
10 to a maximum loss in crop production: the yield and crop enterprise budgets for “dry
11 land” farming areas. More information on how crop yields for different crops
12 respond to various numbers of consecutive days without water (some crops may be
13 more resilient than others) along with the effects of evapo-transpiration could be
14 gathered.

15 **Thermal Power**

16 Modelling suggests that MRRMP-EIS alternatives with additional flow releases relative
17 to No Action (Alts 2, 4, 5 and 6) results in changed frequency and duration of intake
18 operability in both the upper and lower river. In addition to intake operability concerns,
19 temperature issues may be experienced in the lower river. Higher river temperatures
20 may cause thermal power plants to exceed thermal discharge limits and have reduced
21 operational efficiencies; under current conditions, the regulatory and operational limits
22 are approached and sometimes exceeded. If, as a result of changes in flow releases and
23 subsequent storage recharge, river flows in the lower river were reduced during a hot
24 summer period relative to No Action, river temperatures could increase above
25 regulatory and operational thresholds, with reductions in power generation and
26 increased costs to replace reduced power generation and lost capacity during peak
27 power periods.

28 “Thermal Power Technical Report” discusses in substantial detail the information base
29 on which the impacts of the alternatives’ thermal power impacts were estimated. In
30 general, uncertainties associated with the ability to predict intake issues and their effects
31 on thermal generation are considered small. The database of intakes is considered
32 robust, and river stages and reservoir elevations are well understood. However, channel
33 geometry complexities in certain locations may give rise to uncertainties when linking
34 flow and elevation patterns to actual operational difficulties.

35 There is likely low uncertainty concerning the potential impacts of habitat creation (via
36 construction or flows) on thermal power. The EIS notes that most power plants are in

1 urban areas that are well away from any sites likely to be considered suitable for habitat
2 creation and site-specific planning would minimize adverse impacts to sensitive
3 infrastructure such as power plants. Although there are six power plants in the Garrison
4 Dam to Lake Sakakawea reach that could be affected by the creation of ESH habitat, site
5 specific planning would result in relatively small, temporary, adverse impacts.

6 There are important uncertainties concerning thermal impacts, however. These include:

- 7 • There is a limited data set of only 15 usable years of temperature data from the
8 temperature model. Actual river temperatures are an important input into the
9 model and are not systematically collected in a way that would be optimal for
10 monitoring and predictive modelling.
- 11 • The predictive temperature model itself has other uncertainties.
- 12 • There are uncertainties surrounding the calculation of lost capacity value
13 associated with the potential loss of generation from the MRRMP-EIS
14 alternatives.
- 15 • It is uncertain how state regulators would actually act in individual situations
16 when thermal power discharges are in violation of permits. Some power plants
17 have sought variances to maintain operations by showing that their thermal
18 effluent does not have adverse environmental impacts. Other plants would need
19 to derate or reduce power generation to meet NPDES requirements.

20 One of the primary uncertainties concerning thermal power relates to understanding the
21 relationships between operations and temperature at susceptible power plants.
22 Currently, each power plant monitors river temperature locally. However, NPDES
23 permit temperature monitoring requirements differ and are often not required to be
24 undertaken daily. Daily monitoring of river temperatures by power plants and reporting
25 to the USACE (or possibly to USACE via the state water quality regulatory agency) as
26 well as the consistent notification to the USACE of any operational or regulatory impacts
27 to power generation from river temperatures is a necessary component of a monitoring
28 program. The largest single gap in the ERDC temperature model is the availability of
29 historical temperature information at the correct locations and in a uniform format
30 (hourly or daily temperature data). If river temperature monitoring at key locations
31 were to be centralized and optimized with respect to location (e.g. in tributaries as well
32 as around local plant sites), the USACE would not only have a better real-time
33 understanding of the issue but would also improve their future ability to understand
34 how future management changes might affect temperature in the river.

1 To better understand how river bed geomorphic changes (early life stage habitat) affects
2 river temperatures, temperature monitoring at the site level should be undertaken while
3 considering the timing of habitat construction upstream and in proximity to power
4 plants.

5 **Water Supply**

6 MRRMP-EIS alternatives with additional flow releases relative to No Action (Alts 2, 4, 5
7 and 6) generally result in increased frequency and duration of periods with lower
8 reservoir storage (associated with flow releases) and lower river flows (associated with
9 system recharging following a flow release) than would have been the case under No
10 Action.

11 “Water Supply Technical Report” discusses in substantial detail the information and
12 assumptions used to estimate impacts on water supply access from the management
13 plan alternatives. In general, there are uncertainties regarding how water supply
14 managers would react to changing river conditions and the evaluation of impacts only
15 considered one possible approach (use of submersible pumps). During the development
16 of the MRRMP-EIS, intakes showing potential sensitivity to differences in alternatives
17 were researched further on a case by case basis to verify information on intake
18 thresholds etc. Moreover, many of the water intakes in the system, particularly around
19 reservoirs, were upgraded in the early 2000s during the period of low water during that
20 time. These intakes, under most circumstances, would be unlikely to be affected by any
21 changes in flows resulting from the MRRMP-EIS alternatives.

22 The proxy analysis showed that impacts are expected to occur to water supply intakes
23 under current system operations. It was assumed that this impact is being caused by
24 degradation that is occurring in several river reaches and that water supply managers
25 would need to make improvements to the intakes to address the degradation. This
26 degradation is not caused by any changes associated with the Management Plan. The
27 analysis did not attempt to evaluate significant intake modifications that would occur as
28 a result of degradation issues, but instead focuses on incremental changes that would
29 occur as a result of the Management Plan.

30 The accuracy of the existing inventory of water supply intakes and reaction of managers
31 to changing river conditions could be further improved through the use of interviews
32 with water supply managers. Many such managers have already been interviewed
33 during the MRRMP-EIS development. The additional interviews would seek to further
34 confirm the operation and operability of certain intakes during periods when predictive
35 modelling indicates problems should be anticipated. It would confirm the capacity of

1 each intake and would probe further about operators' experiences under specific water
2 conditions.

3 **Navigation**

4 Changing water management patterns resulting from the EIS alternatives could affect
5 the ability of commercial vessels to transport goods on the Missouri River. Alternatives
6 with additional flow releases relative to No Action (Alts 2, 4, 5 and 6) generally result in
7 differences in frequency and duration of periods with lower river flows (associated with
8 system recharging following a flow release) than would have been the case under No
9 Action.

10 The "Navigation Impact Analysis Technical Report" discusses in substantial detail the
11 data and methods employed to estimate the navigation impacts from the alternatives. In
12 general, uncertainties associated with predicting navigation impacts are considered to
13 be relatively low for a study of this type, because the estimation methods followed for
14 this analysis have been developed, tested and confirmed over a number of decades by
15 the USACE that are outlined in Engineering Regulation (ER) 1105-2-100 Planning
16 Guidance Notebook, April 2000.

17 Nevertheless, some uncertainties remain. There is uncertainty about the precise flows
18 that are required for commodities to move on the water. For example, the Waterborne
19 Commerce Statistics Center (WCSC) data shows sand and gravel commodities moving
20 on the water when less than minimum service is occurring, but Master Water Control
21 Manual Missouri River Review and Update Study, Volume 6A-R: Economic Studies
22 Navigation Economics (Revised) (1998) states the towing companies would be seriously
23 impacted by flows less than minimum service.

24 The MRRMP-EIS analysis assumed that water traffic impacted by low water events has
25 the potential to move off the water, which may not always be the case. It assumes a flat
26 level of future demand, which may not be the case.

27 Uncertainty is also introduced through the use of transportation savings functions and
28 assumptions that were necessarily based on an economic study from 1998. Though a
29 transportation rate analysis was published in 2002, the last comprehensive study
30 relating changes in flows to shipping and related economic issues on the Missouri was
31 published in 1998. A new study could update the relationship between changes in flows
32 and transportation rate savings by particularly focusing on the costs associated with
33 shipping and the next least cost option. A comprehensive study could be expensive, but
34 the need for such an approach could first be tested through the use of a pilot study that

1 would investigate a smaller number of movements to explore the additional value of
2 updating rates and costs for all movements. If the pilot study reveals that the 1998
3 values can simply be scaled, then the larger study might not be necessary.

4 **Hydropower**

5 “Hydropower Technical Report” discusses in substantial detail the information base on
6 which the impacts of the alternatives’ hydropower impacts were estimated. In general,
7 uncertainties associated with predicting hydropower impacts are considered to be
8 moderate because, though actual hydropower generation is continuously monitored and
9 analyses comparing this information with river flows are routinely undertaken, the
10 modeling and energy prices used for the analysis contain some inherent uncertainties
11 detailed below.

12 One source of uncertainty in predicting impacts to hydropower appear to be
13 assumptions made in shaping modeled daily average flows into hourly flows in order to
14 better simulate generation value. The differences between the alternatives are very
15 small in percentage terms. Because the NED values associated with hydropower are
16 large in absolute terms (in the hundreds of millions of dollars per year), even small
17 inaccuracies could give rise to large errors in dollar terms. However, although absolute
18 values are important for decision making, it is likely that any inaccuracies in
19 establishing the absolute generation value would apply similarly across all alternatives.

20 Another source of uncertainty in predicting impacts to hydropower is the assumptions
21 made in energy and capacity prices. There is a lot of uncertainty and volatility in the
22 energy market pricing and forecasted energy prices and energy prices can shift
23 dramatically from year to year. These changes could potentially greatly impact the
24 absolute value of each alternative and the differences between them. However, these
25 changes should not affect the ranking of alternatives and the relative differences
26 between each alternative and the no action alternative.

27 No additional information collection is therefore recommended at this time.

28 **Flood Risk Management**

29 The “Flood Risk Management Environmental Consequences Analysis Technical Report”
30 discusses in substantial detail the information base on which the impacts of the
31 alternatives’ flood risk management impacts were estimated. In general, uncertainties
32 associated with predicting flood risk management impacts are relatively low because the
33 inventory of structures that could be affected by flooding is considered relatively robust.

- 1 Considerable effort was made as part of the Management Plan to confirm the accuracy
 - 2 of elevations for locations that appeared to show differences between the alternatives.

 - 3 Groundtruthing predicted impacts will be of key importance for FRM if flow actions
 - 4 were contemplated. However, there are opportunities to begin groundtruthing flood risk
 - 5 management modelling predictions under the preferred alternative, by monitoring the
 - 6 nature and extent of damage associated with assets under certain circumstances,
 - 7 particularly in any high flow years that may happen to occur in the early years of the
 - 8 implementation of the AMP. As previously noted, however, given the dynamic nature of
 - 9 the river channel, consideration must be given to the temporal relevance of
 - 10 groundtruthing activities.
-
- 11 For sites with the highest associated dollar impacts, a detailed groundtruthing study
 - 12 might also consider alternatives to accepting the damages associated with flooding (for
 - 13 example by moving a sensitive asset, by protecting it or by making it less vulnerable to
 - 14 flooding waters).

15 **Other Issues**

16 Working with USACE during the implementation of the Plan, the HC Team could
17 identify other areas that would benefit from the collection of the kind of information
18 outlined here. These requests should be subject to the screening methodology outlined
19 above.

20

21 *5.5.5.2 Important or necessary to resolve before undertaking an important management*
22 *action*

23 Some uncertainties are critical to overcome before a decision could be made to
24 implement a decision authorizing a flow release include the following:

25 The channel capacity of inter-reservoir reaches varies depending on the amount of
26 aggradation or degradation that occurs during periods of low or high runoff, and, in
27 some locations, downstream pool levels and tributary inflows. Consequently, high flow
28 releases from reservoirs must be managed to minimize impacts to downstream private
29 property. The preferred alternative includes a provision for a Level 2 in-river spawning
30 cue release test. If included in the Record of Decision (ROD), this test would consist of a
31 one-time release from the System after year 8, if Level 1 studies do not provide a clear
32 answer on whether a spawning cue is important. Additionally, flow actions for the

1 creation of ESH were investigated, but not included in the preferred alternative for the
2 Draft MRRMP-EIS.

3 The MRRMP-EIS analysis shows that the proposed flow for pallid sturgeon and the ESH
4 creation flows, as currently defined, could potentially inundate private lands along the
5 Missouri River, in the reach between the Ft. Randall and Gavins Point dams, as well as
6 downstream of Gavins Point due to coincident flows from tributary rivers. This impact is
7 one the USACE has sought to minimize in its selection of its preferred alternative.
8 USACE will continue to analyze the flow's potential impact on flood risk management
9 and if these impacts are covered by any existing easements. Where an easement does
10 not already exist, the MRRP will continue to effectively strategize how to 1) address
11 uncertainties regarding potential impacts, and 2) minimize the impacts prior to any test
12 flow release. Minimization through acquisition of easements will be investigated,
13 though current authorities and funding for such efforts are extremely limited.

14 Given the relatively high impacts associated with temperature in the lower river for
15 thermal power under Alternative 2, it would be important to reduce this uncertainty
16 before undertaking a nesting flow operation. This could occur as part of the temperature
17 research mentioned above.

18 The MRRMP-EIS analysis indicates that some increased flood risk may exist with the
19 ESH and spawning cue related actions. Section 5.8 explores some modifications to
20 alternative definitions that might help reduce some of these impacts if they were ever to
21 be implemented, and it is noted there that additional water inflow monitoring in certain
22 tributaries may help mitigate some of the additional risk posed by these operations. This
23 could be undertaken prior to a flow release being implemented as minimization
24 measures.

25 5.5.5.3 *Monitoring of HC issues that could be only undertaken in the event of a flow*
26 *modification*

27 If flow releases were to be implemented, a program of field-based groundtruthing
28 around sensitive assets may help reduce remaining uncertainties, though these would
29 need to be carefully targeted to ensure that the value of information justified the
30 expenditure. This suggests an exercise could be undertaken as part of the Plan involving
31 the HC Team and USACE analysts to identify and prioritize specific groundtruthing
32 activities to undertake during a specific planned flow event. The selection of activities
33 would depend on the precise flow under evaluation. For example, different sites and
34 features may be threatened under recruitment flows, vs ESH spring release flows versus
35 ESH fall release flows etc. Even across the spring release alternatives 2, 4 and 6, the

1 different nature and timing of the releases may imply different monitoring regimes for
2 HCs.

3 Therefore, specific groundtruthing studies would need to be designed by the Technical
4 and HC Teams and adopted by the USACE nearer the time of potential implementation.

5 **5.6 Evaluating Effects of Actions on HCs**

6 **5.6.1 Evaluation of Human Considerations in an annual cycle**

7 The annual planning cycle begins with an assessment phase in which the AM Technical
8 Team reviews the current status of system, bird, fish and HC metrics and indicators. The
9 team would also work with the MRBWMD to assemble information on the upcoming
10 year's hydrological and meteorological situation. Typical information compiled would
11 include (but not be limited to):

- 12 • Storage, snowpack, long-term runoff and regulation forecasts, current reservoir level
13 status etc.,
- 14 • Updates on recent habitat availability and trend, as well as physical changes on the
15 river (e.g. any significant changes resulting from high flows, previous years' physical
16 works, new information on aggradation or degradation, etc.,)
- 17 • Changes in species condition and outlook in the context of the previous year and
18 over the long term. This would include an assessment of the quantity of bird habitat
19 available at various locations, for example, as well as habitat and population
20 forecasts including sensitivity and scenario analyses thereof using the same
21 predictors employed by the MRBWMD in developing the AOP.
- 22 • Status of any Level 2 experiments being undertaken on the system or planned for the
23 coming year.
- 24 • Results of research activities that might offer insight into new opportunities or
25 trigger implementation of any identified management actions; results of lines of
26 evidence assessments related to hypotheses that might result in the rejection of a
27 hypothesis.
- 28 • Status of HC metrics/indicators and any major changes to HC situations, with a
29 special focus on multi-year considerations (e.g. are there any notable multi-year
30 drought or flood impacts being felt by a particular interest group).
- 31 • Any significant HC activities or conditions that might limit potential management
32 actions (e.g. scheduled navigation traffic to Sioux City).

33 Once the season is over, an evaluation of the previous season's predictions would be
34 informative for planning efforts for the following year. Such a review would likely be
35 more intensive in the early years of the plan after novel management actions potentially

1 involving HC impacts have been undertaken. Over time, as experience and knowledge of
2 the actual impacts of these management actions is gained, the intensity and rigor of the
3 post-season evaluation may be expected to reduce.

4 The nature of a post-action review of impacts for the ESA species are discussed in
5 Chapters 3 and 4. Various issues related to HCs including those outlined in the following
6 sections may also be considered as part of the review.

7 5.6.1.1 *Comparison of annual predictions versus monitored impacts.*

8 Although not possible in every case, it should be possible in some cases to compare the
9 range of outcomes that were predicted from a particular management action with the
10 monitored (i.e. measured) impact on a given HC. This is most readily done for proxy-
11 style indicators of the type that predict the number of days above a threshold thought to
12 be associated with an impact.

13 A post-season review could investigate comparisons of the predicted versus observed
14 proxy indicator levels and predicted versus observed harm (or benefit) observed on the
15 ground. In some cases such evaluations might be straightforward, but in many
16 situations more involved analysis will be required. Over time, calibration could occur
17 between the predicted outcomes and measured ones; however, establishing the validity
18 of a causal relationship between actions and measured response or impacts would be
19 necessary before decisions based on the information could be used.

20 As discussed above, such comparisons would be greatly facilitated by the ability to ‘hind-
21 cast’ estimates of what would have happened without the operation, particularly in cases
22 involving flow actions. Results of these comparisons would be shared with the
23 appropriate technical team, the Management Team, and the HC WG and would be
24 discussed, at a minimum, at the Fall Science Meeting and/or the AM Workshop.

25 To effectively monitor HCs, methods may need to be developed to integrate select HC
26 indicators into operational models in order to provide real time or short term forecasts
27 of potential effects based on operational decisions. This could be for information
28 purposes only, or may factor into the decisions themselves, depending on the outcomes
29 of analyses, selected management actions and monitoring agreements, and evaluations
30 of the resulting data.

31 A parallel may be drawn here to the hypothesized impacts of management actions on
32 birds and fish discussed in Chapters 3 and 4. In these chapters, hypotheses are made
33 about birds and fish might be affected by certain changes in physical conditions. The

1 steps of AM are undertaken to test how well observations match the predictions made in
2 advance in order to learn how to improve predictive capacity.

3 Similarly, the tools described above – H&H modeling, proxy measures and full
4 performance measure analyses – are essentially *hypotheses* about how HCs will be
5 affected by physical and/or operational changes. A monitoring and AM program can be
6 used to assess how HCs are actually affected by any changes to the flow regime, to
7 compare these observations with predictions, and to evaluate appropriate responses to
8 the findings.

9 The adaptive nature of bird and fish actions means that managers may wish to try
10 particular combinations of tools that are within the decision space created by the MRRP
11 and for which modelled predictions would appear to be acceptable, but for which precise
12 estimates of HC implications cannot be made. Decisions about which HC outcomes
13 might require monitoring will be affected by considerations such as the degree of
14 uncertainty, associated risk, likelihood of that information affecting decisions, costs,
15 resource availability, etc.

16 5.6.1.2 *Comparison of longer term predictions versus monitored impacts.*

17 Some impacts will not be able to be determined on an annual basis, but will instead
18 require longer term assessments. As with the ESA species, it may be difficult to quantify
19 or attribute MRRP actions to impacts on certain HCs, and careful thought will need to
20 be given to the selection and development of specific HC measures to monitor to ensure
21 that the data collected can be used for this purpose. Advanced analytical and / or 'big
22 data' techniques may be required in some cases. These methods should be developed by
23 the HC Team in collaboration with the USACE during the early years of implementation
24 of the Plan. As with the analysis results described above, the long-term performance
25 would be shared with and discussed by the appropriate AM Teams and the HC WG.

26 The evaluation phase sets the context for the planning and design step. The plans for the
27 coming year are considered and, if necessary, Oversight level decisions are made.

28 5.6.1.3 *Define species needs for the coming year*

29 Under the selected alternative that will be described in the ROD, there are inherent
30 variations in implementation that are still compliant with NEPA for a programmatic
31 EIS, like the MRRMP-EIS. For example, IRC habitat development is evaluated in the
32 MRRMP-EIS and is currently part of the preferred alternative. However, the design of
33 IRC habitat could evolve over time based on information gathered through the AM
34 process. Site specific design may require additional NEPA coverage before construction

1 of IRC habitats. The need for additional NEPA analysis will be determined by USACE
2 on a case by case basis.

3 For actions that deviate substantially from the ultimately selected alternative described
4 in the ROD, additional steps to comply with various regulations will likely be required,
5 but again such determinations will be made on a case by case basis MRRMP-EIS (see
6 Section 2.2.4). For birds, this may include considering, for example, whether a flow
7 release for ESH creation is likely suitable (or necessary), or whether conditions better
8 suit or can be met using mechanical construction or some combination of the two. If the
9 necessary authorizations are in place, a summary of any special monitoring
10 requirements for the year ahead should be developed at this point of analysis, along with
11 high-level costs so monitoring of the action could occur.

12 5.6.1.4 *Where appropriate, define alternative means of meeting species goals*

13 Even under the preferred alternative, there are usually alternative means available for
14 meeting the same needs. If the options available are expanded to include some of the
15 actions evaluated in the MRRP-EIS but not in the preferred alternative (see Section
16 2.2.4), different approaches may exist. For birds, this may include considering, for
17 example, whether a flow release for emergent sandbar habitat creation is likely suitable
18 (or necessary) in the year ahead, or whether conditions better suit or can be met using
19 mechanical construction or some combination of the two. Note that although the MRRP
20 might have authorized the use of flows up to a particular scale as an *option* to create bird
21 habitat, it may not be a feasible, preferable or otherwise appropriate in any given year
22 (for a variety of reasons). A summary of any special monitoring requirements for the
23 year ahead should be developed at this point of analysis, along with high-level costs.

24 5.6.1.5 *Estimate consequences of alternatives*

25 At this stage, a predictive assessment of the consequences of the one or more
26 alternatives should be made on the following:

- 27 • The ESA species – are the alternative(s) sufficient as part of the multi-year program
28 to comply with the Biological Opinion and the findings contained therein?
29 • HCs – what are the predicted impacts of the alternatives on HCs that are expected to
30 be affected by them? Are these predictions within the decision space enabled in
31 MRRP AM Plan?
32 • What are the predicted impacts of the alternatives on other in-river activities not
33 accounted for in the HCs, including ongoing Level 2 experiments or other USACE
34 management actions on the river that could be affected differently by the
35 management actions?

- 1 • Are there any other management or logistical considerations for preferring one
2 alternative over another?
- 3 These questions lend themselves to an abbreviated form of PrOACT analysis, though
4 this need not suggest an excessively onerous analytical undertaking, and could instead
5 be a simple assessment of pros and cons of each of the alternatives. The important point
6 is to have a process that recognizes that any given alternative carries with it a range of
7 complex consequences that need to be considered each year.
- 8 Importantly, even if only one alternative is being proposed for the year, some form of
9 prediction of its consequences (within an appropriate range of uncertainty) should be
10 made. This information will be used in subsequent steps of the annual AM planning
11 cycle and will inform monitoring needs (if any).
- 12 Note that methods to estimate HC impacts would need to be in place; the models used
13 for the proxy analysis may or may not be the same as those required for this purpose.
- 14 *5.6.1.6 Evaluate tradeoffs and develop an approach for the coming year*
- 15 The selected management actions/alternatives, along with supporting research and
16 monitoring identified for the year ahead should be considered by the Management Team
17 and MRBWMD and, with appropriate consultation with stakeholders as outlined in
18 Chapter 2, a corresponding recommendation provided to the agency Oversight in the
19 form of a draft WP identifying the proposed management action. The plan is presented
20 at an annual forum of the MRRIC, who may provide comment and/or make a consensus
21 recommendation regarding the plan.
- 22 *5.6.1.7 Prepare detailed Work Plan for the coming year*
- 23 As a final planning step, agency leadership at the Oversight level decides on the course
24 of action and the decisions are incorporated into a final Work Plan as per the current
25 situation and the Work Plan is made available for stakeholder review. In the event any
26 flow measures are included in the plan, the appropriate additional coordination, as
27 described in Chapter 2 and as required by other policies would occur (including, as
28 required, modifications to the Master Manual), and those plans would be incorporated
29 into the AOP by MRBWMD. Decisions on the general approach to the year ahead,
30 subject to suitable appropriations and conditions, are finalized at this point.

1 **5.6.2 Model updating and validation analyses**

2 A primary mechanism for capturing and applying learning is incorporating new
3 information collected during the previous year, as appropriate, into the models. This
4 includes a) assessments based on monitoring data updated on an annual basis, b)
5 information from targeted studies or short-term monitoring (e.g. geomorphic
6 assessments following flow events) and c) information from external studies deemed to
7 be of sufficient quality and relevance.

8 Model validation procedures test model accuracy and precision by comparing model
9 predictions with observations that were not used to parameterize the model. Periodic
10 updates to the models may be required to reflect changed conditions in the system, new
11 System operations, improved understanding, etc. Validation of existing models and any
12 model updates in the future is strongly encouraged, subject to consideration of the
13 sensitivity and accuracy of the models and the extent to which model errors might affect
14 decisions.

15 Recommendations for model updates or validation may be made by the HC Team to the
16 Management Team. The updates and validation activities will generally be conducted by
17 the Technical Team, but they may consult with the HC Team and/or Management Team
18 about the use of additional information and should report on the effects of the changes
19 being made as relevant to decision-making.

20 **5.6.3 Trade-off analyses to support Work Plan development**

21 There are several forms of economic and/or decision analysis that could be undertaken
22 to help support the evaluation of alternatives. This is discussed further in Chapter 2 (see
23 Section 2.4.5.2) and in Section 5.7.3.

24 **5.6.4 Incorporation of new information**

25 Research that is conducted over the course of the year is summarized in the annual AM
26 report. MRRP-funded research will typically be reported upon in the Fall Science
27 Meeting and the Annual AM workshop. Relevant non-MRRP research findings will also
28 be discussed in the report when available, with consideration given to the level of
29 QA/QC and peer-review or related evaluations such findings have undergone and to the
30 design and strength of studies.

31 Occasionally, new or unexpected information might become available that has the
32 potential to significantly alter some aspect of management under the MRRP and which
33 is not captured in the annual AM science process. This may be a matter of timing

1 (urgent findings which miss the AM reporting cycle) or because the information was not
2 identified by the Technical or HC Teams. Such information would be vetted and
3 addressed through the process described in Section 2.5.4. Important insights emanating
4 from the vetting process would be incorporated into the AM process in the same way as
5 other monitoring and assessment results.

6 **5.6.5 Ancillary information**

7 Additional information that reflects learning or provides important insight into decision
8 making but was not targeted through specific monitoring or studies should be captured
9 and synthesized as part of the evaluation process. Examples of ancillary information
10 include: observations about flood conditions on agricultural lands during a flow event;
11 local changes in bed level that might reflect shoaling or scour; measurements of stage
12 relative to water intakes over a low flow period; or patterns of erosion caused by flows
13 within normal ranges. To the extent possible, such information should be quantified and
14 systematically reported along with monitoring data in annual reports. Other
15 information sources can be included if appropriately vetted (see section 2.5.4). Such
16 information can be used to adapt local management actions, help explain patterns in
17 monitoring data (e.g. multiple local factors could result in unusually high or low stage in
18 a reach), and identify questions and hypotheses for future research and analyses. The
19 quality of ancillary information will vary and may be subject to bias due to how factors
20 are observed and when they are noted and should be assessed when data is collected
21 and/or compiled. Ancillary observations may indicate the need for more systematic
22 monitoring of factors not previously monitored.

23 **5.7 Decisions under AM**

24 **5.7.1 Decision making process**

25 The USACE has historically engaged in various forms of passive AM by incorporating
26 information about the effects of management actions on HCs into short-term and
27 longer-term decision making when managing the System. At present, the incorporation
28 of new information is undertaken within the discretion of the MRBWMD, sometimes
29 with review from stakeholders during AOP consultations. Appendix I of the Master
30 Manual presents and discusses various ways in which the USACE undertakes AM on the
31 Missouri River. These decisions are generally manifest as part of the AOP process.

32 The annual decision-making process for the MRRP is described in full in Section 5.6.1
33 with a brief summary focused on the role of the HC Team provided here. Following the
34 evaluation phase and the release of the Draft Annual AM Report, the HC Team meets to
35 review monitoring and assessment related to HC issues and to make recommendations

1 regarding needed monitoring or assessment in upcoming years. Activities for the
2 current FY are already set, and budgets have been established for FY+1. The HC Team
3 may identify priority adjustments to the plans for FY+1, but their focus is on specific
4 planning for FY+2 and general planning, including estimates of budget needs, for FY+3
5 and FY+4.

6 In considering monitoring and assessment needs, the HC Team is encouraged to apply
7 the factors outlined in Sections 5.5 and 0. Recommendations from the HC Team are
8 provided to the Management Team for their consideration in formulating the Draft
9 Work Plan. The Draft Work Plan is taken under consideration by the agencies and
10 MRRIC, and the HC WG may provide draft recommendations to the MRRIC to support
11 that effort, either separately or as part of a combined report with the Bird and Fish WGs.

12 The strategy outlined above parallels the activities of the Bird and Fish Teams except
13 those teams are also providing priority recommendations on management actions. The
14 HC Team does not weigh in on management actions as that is a responsibility of the full
15 MRRIC. Decisions on which management actions get implemented are made by the
16 USACE with input from the USFWS and MRRIC, potentially including consensus
17 recommendations by the MRRIC. The process through which MRRIC engages in these
18 decisions is outlined in Section 0.

19 **5.7.2 Decisions regarding monitoring and assessment for HCs**

20 As part of the annual process to update the Work Plan, the HC Team will revisit HC-
21 related monitoring and assessment activities and provide recommendations on priority
22 needs, including the cessation of monitoring when information and knowledge is
23 sufficient to support decisions. The Missouri River is a complex system and a large
24 number of endpoints could in theory be monitored. All monitoring and subsequent
25 analysis of data requires resources that could otherwise be redirected. Issues should not
26 necessarily be monitored simply because there would be some value to knowing.
27 Instead, it is important to think carefully about what might constitute the highest possible
28 value for money when evaluating monitoring possibilities.

29 The factors listed in Section 5.5.2 and the process outlined in Section 5.5.3 provide a
30 starting point for the HC Team in considering monitoring and assessment needs. The
31 HC Team is encouraged to refine the approach and to update the guidance in this AMP
32 to reflect the process and factors employed following procedures outlined in Chapter 2
33 for updates to the AM Plan. Feedback from the other teams, particularly the
34 Management Team, and from the MRRIC and agency Leadership should factor into
35 decisions regarding the approach to the Team's recommendations.

1 **5.7.3 Decisions regarding the implementation of the preferred alternative**

2 Implementing the preferred alternative will require a large number of decisions to be
3 made over many years. The institutional context for these decisions is described in
4 Chapter 2 and their technical subject matter is described in Chapters 3 and 4. This
5 section discusses how human considerations might or might not be incorporated.

6 The majority of decisions outlined in Chapter 3 and Chapter 4 that are applicable to the
7 preferred alternative have relatively few direct implications for human considerations.
8 There are numerous technical judgments and decisions to be made around each stage of
9 research study assessment, design, implementation, monitoring and evaluation cycle
10 that, for the most part, concern issues only of science. Some such decisions may have
11 implications for HCs ultimately (e.g. decisions on overall bird status evaluation
12 judgments, decisions to revise targets or metrics, decisions to move from Level 1 to Level
13 2 research programs), but HCs are not (and should not) be a consideration in these.

14 Some decisions within the scope of the preferred alternative that do have the potential
15 for HC impacts include those concerning:

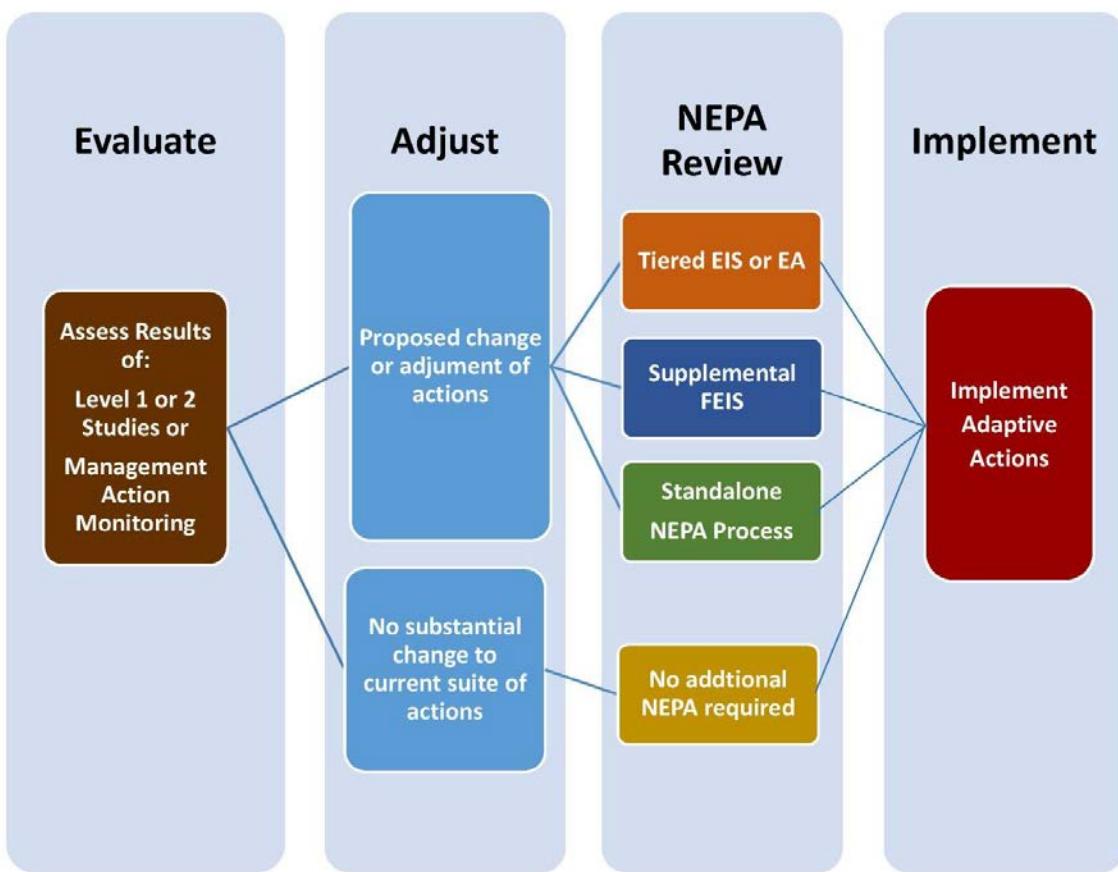

- 16 • Siting and design of habitats for mechanical construction;
17 • Mechanical habitat construction timing and approach;
18 • Human access management in sensitive areas for birds;
19 • When and how to implement a pallid spawning cue test flow, if required.

20 Emergent sandbar habitat for birds and spawning habitats for pallid sturgeon are in-
21 river and their construction has relatively limited implications for human
22 considerations. Pallid sturgeon IRC complexes require bank-side land, but have specific
23 geophysical requirements that suggest biological functional priorities may dominate
24 consideration of all but the most compelling HC issues when deciding upon preferred
25 locations. Specific habitat construction siting decisions may be amenable to Cost
26 Effectiveness and/or Incremental Cost Analyses. Candidate locations would be first
27 identified using biological criteria then cost effectiveness-based methods used to
28 identify the most cost-efficient combination of locations to meet the required biological
29 need. Locally-important site issues (e.g. addressing concerns around potential for
30 impacts on intakes, potential for ice-jam effects, etc.) or other local site considerations
31 would be considered on a site-by-site basis during the planning and PED phases, and
32 would be addressed through a) the Work Plan development process (by the
33 Implementation-level and Management teams, and b) the site-specific NEPA activities
34 or compliance with other laws.

- 1 As discussed in Chapter 3 of the MRRMP-EIS, there is potential for impacts to various
2 HCs from mechanical habitat construction. Of particular concern are issues related to
3 the potential for site-level flooding and/or riverbed changes leading to localized
4 problems for intakes or navigation, water quality, and general construction disturbances
5 of noise and traffic. These issues will be avoided or minimized through the application of
6 established Best Management Practices (BMPs) long established by the USACE as well
7 as the planning process. Similarly, human access management for the protection of bird
8 habitat would be undertaken in ways that minimize unnecessary inconvenience using
9 established USACE protocols.
- 10 As an example of how local site issues might be incorporated into decision making
11 during the implementation of the preferred alternative, consider the situation in which
12 bird habitat (ESH) creation is needed in the reach between the Garrison Dam and Lake
13 Oahe. Flood risk management concerns have been expressed for this reach given
14 uncertainties regarding the effects of ESH on the location, rate and magnitude of ice
15 formation in that reach. In such a case, addressing the decision using a structured
16 decision making technique (such as either a Multiple Account Evaluation (MAE) or
17 Multi-Attribute Utility Analysis) could help provide a framework for engaging decision
18 makers, scientists and stakeholders in understanding the trade-offs between competing
19 alternative approaches. The exact criteria to consider would be specific to the decision
20 context and would need to be developed in collaboration between the Bird and HC
21 Team. Such a framework would allow the open discussion of construction costs,
22 biological performance, flood risk tolerances and any other issues deemed worthy of
23 consideration.
- 24 The preferred alternative provides for the potential use of a Level 2 spawning cue flow in
25 the first increment, to be implemented only in the case that 1) science cannot resolve the
26 question of whether spawning cue events might be helpful without resort to field data
27 and 2) a suitable flow from which to study this issue has not arisen during the normal
28 course of operations.
- 29 A spawning cue flow action of this type was studied in detail in the MRRP-EIS in
30 Alternative 6 and its range of potential effects on HCs has been estimated.

31 **5.7.4 Decisions regarding the implementation of new actions outside the preferred
32 alternative**

33 As discussed in Section 2.2.5 and illustrated in Figure 91, actions analyzed in MRRMP-
34 EIS alternatives but that are not in the preferred alternative could be nevertheless be
35 implemented, though this would require a new decision document and could require
36 Master Manual modification (as outlined in Attachment 5 of Appendix A).

1

2 Figure 91. Integration of the NEPA Compliance Process in the AM Framework

3 An example of a situation that could require such steps could be as follows: in the years
 4 after a ROD is issued, no high flows naturally occur on the river that create emergent
 5 sandbar habitat. Instead, flows in the river steadily erode the existing sandbars, and
 6 those sandbars that do remain become mature and cannot effectively be made
 7 sufficiently productive through vegetation and predator management activities. Bird
 8 monitoring shows declining fledge ratios, negative lambda values and declining
 9 populations; the bird status and need matrix (Section 3.5.3) indicates that bird
 10 objectives will not be met and there is a need to rapidly increase the rate of habitat
 11 creation. In short, it is discovered that action must be taken to increase ESH.

12 In this scenario, the first course of action would be to bolster mechanical habitat
 13 construction to achieve the targeted acreages. In the event mechanical construction is
 14 projected to fall short of targets and a continued deficit is projected, a decision would
 15 likely be made to consider what actions outside of the preferred alternative could be
 16 undertaken. One option might include consideration for actions outside the ROD but
 17 considered in the MRRMP-EIS (e.g. an ESH flow release, either in the spring or fall

- 1 [examined in MRRP-EIS Alternatives 4 and 5, respectively] or the use of a reduced
2 nesting flow [a component of Alternative 2]). Alternatively, novel solutions that have
3 emerged as a consequence of new knowledge or additional analyses could be considered.
- 4 The decision to pursue alternatives outside the ROD would have important implications
5 for the MRRP and potentially some HCs. Either approach would require additional
6 actions and decisions before it could be implemented (see Section 2.2.5). There are two
7 general approaches to help minimize negative impacts to HCs.
- 8 The first would involve consideration of the use of a number of alternative definition
9 modifications that have been conceptually developed to protect human considerations
10 from the most negative consequences associated with actions that were examined in the
11 MRRMP-EIS. These potential modifications are discussed in Section 5.8.
- 12 The second would involve the use of a structured decision-making approach to explore
13 the relative advantages and disadvantages of different options. This would mirror to
14 some extent the process undertaken to evaluate alternatives under the MRRMP-EIS,
15 though with important differences. As a first step, feasible alternatives to meet the
16 biological need would be identified, working initially from the actions explored in the
17 MRRMP-EIS.
- 18 An analysis would be then undertaken to estimate the impacts of these alternatives on
19 the range of HCs. The nature of this analysis would depend on the context for the
20 decision. If a quick decision is needed, the HC team would work to assemble the best
21 available evidence from the MRRMP-EIS, amended as required from learning in the
22 intervening time, to estimate the range of biological, program management HC and
23 other impacts associated with each approach.
- 24 Because certain parameters about the actual situation would be better known, the
25 uncertainty around effects to HCs may be lower than in the MRRMP-EIS, which
26 considers an 82 period of record. For example, system storage (high or low) is known to
27 be a strong influence on some HCs – and since system storage varies over multiple
28 years, in any given year that variable will be approximately known.
- 29 In either case, decision makers and, time permitting, MRRIC, would be informed to
30 understand the trade-offs involved and given an opportunity to express preferences for
31 one approach over another.
- 32 The exact nature of the analysis to be used and the HC performance metrics that would
33 be most appropriate cannot be determined at this time. However, a task for the HC

1 Team at the initiation of the AM Plan could be to investigate the types of performance
2 metric that may be available for each HC, and which might be used under varying
3 circumstances decision-making circumstances. In some cases, economic methodologies
4 from the MRRMP-EIS might be readily transferrable. In others, proxy metrics or curves
5 relating proxy indicator values to economic values may be developed.

6

7 **5.8 Potential Alternative Definition Modifications Intended to Reduce**
8 **Impacts to HCs**

9 **5.8.1 Context**

10 The analysis of MRRMP-EIS alternatives provides a rich source of information for
11 understanding the specific circumstances that give rise to the most acute impacts to
12 HCs. An analysis examined the impact on HCs in each year of the period of record,
13 focusing on the net change in NED for each resource area, and sought to explain why the
14 most negative impact years occurred. RED and OSE impacts are typically correlated to
15 NED impacts for any given resource area. The analysis found that for most HCs there
16 were various circumstances created by the alternatives that give rise to a small number
17 of unusually high impact difference years. In discussions with MRBWMD, several
18 proposed amendments have been conceptually outlined that it is thought might better
19 inform decisions that could help avoid or reduce the impact of each of the actions
20 associated with each of the MRRMP-EIS alternatives if they were to be implemented.
21 These proposed changes do not *concern activities included in the preferred alternative*
22 (*with the exception of the potential spawning cue test flow*), but do address actions that
23 could be implemented in the course of the plan under the circumstances outlined in
24 Section 5.7.4 following procedures laid out in Section 2.4.5 and described more
25 generally in Chapter 2.

26 Each potential modification proposed here is seeking to address special circumstances
27 created by the alternatives based on information that would be available at the time (i.e.
28 without requiring knowledge of how the future will unfold, as is possible in modelling
29 exercises). Some are amendments that could simply be written into an alternative's
30 definition (e.g. never allow releases to go below x) or require other modifications to
31 practices (e.g. more targeted tributary monitoring).

32 With a small number of minor possible exceptions, the proposed modifications do not
33 influence the severity of the worst absolute impacts to HCs. The largest absolute impacts
34 to HCs tend to occur under extreme wet or dry hydrological years (natural variances),
35 and in those situations the EIS alternatives tend to behave identically and in tandem

1 with the No Action alternative because there is very little operational scope for
2 discretionary decision making in these circumstances. Flow releases from Gavins point
3 using 2011 data, for example, are essentially identical across all alternatives during the
4 period of concern. This is because all EIS alternatives have rules embedded in them that
5 are intended to avoid making extreme situations worse. All alternatives have rules that
6 seek to avoid exacerbating high flood risk situations, or that prevent the use of flow
7 releases to create habitat when system storage is low.

8 Instead, the proposed modifications proposed here are seeking to avoid or mitigate
9 larger impacts relative to the impacts that *would have been experienced under No*
10 *Action*. These differences tend to occur in years that are wetter or drier than average, or
11 when system storage is close to but above thresholds permitted for flow releases.

12 These potential modifications should be considered *suggestions for discussion purposes*
13 only until their full range of implications are better understood. Changing any element
14 of an alternative's behavior and definition will create a chain of impacts that it is
15 impossible to understand without further modelling. Also, each time a flow operation
16 for endangered species is abandoned or foregone out of consideration for HCs, the
17 ecological benefits of that alternative to the endangered species are also foregone (and in
18 some cases made worse). More modelling would need to confirm the net benefits of
19 these rules prior to being implemented.

20 For this reason, the potential modifications are presented as *conceptual outlines* and
21 *without proposed specific parameters*. These would need to be established through
22 further analysis and with consideration given to the risk tolerances (for species benefits
23 versus HC benefits) of decision makers.

24 If the preferred alternative in the Draft EIS is selected for this plan, there would be
25 opportunity to perform such analyses in preparation for possible future implementation
26 of alternatives with flow releases.

27 **5.8.2 Methodology for identifying the proposed modifications**

28 Each resource area was carefully examined to identify data years with the largest
29 positive and negative differences from No Action. Charts for each that aligned impact
30 years with flow release years were developed and studied (examples follow in the
31 description below). For all of the larger differences, HydroViz was consulted to help
32 understand precisely what circumstances were leading to the unusually large impact. In
33 some cases, there is an obvious and direct relationship between a flow release and an
34 impact on a resource area. For others, the impact mechanism is subtler and requires

- 1 study of sequences of years of hydrology differences between an alternative and No
2 Action to understand.
- 3 Once the circumstances behind the large impact were understood, discussions with
4 USACE Water Management helped establish whether the impact might be avoidable
5 using minor amendments to the alternative definition or by another mechanism. In
6 some cases, differences between No Action and a flow alternative could be attributed to
7 minor modelling inaccuracies or issues could be resolved readily using the operational
8 flexibility already permitted within the Master Manual.
- 9 In developing this analysis on a resource-area by resource area basis, it became clear
10 that certain circumstances were affecting multiple HCs in the same way. One issue and
11 its associated potential mitigation identified during an analysis of impacts on irrigation
12 was found to be equally effective for reservoir recreation, for example. For this reason,
13 this section is structured through a presentation of the rules themselves rather than on a
14 resource-area basis, although they are typically illustrated with reference to only one
15 HC.
- 16 **5.8.3 Possible Alternative Definition Modifications Intended to Reduce Impacts to
17 HCs**
- 18 5.8.3.1 *"ESA species population and status considerations"*
- 19 As modelled, alternatives' flow releases are assumed to occur whenever the hydrological
20 conditions permit under the rules of an alternative. No consideration is given to whether
21 there is an actual biological need for such releases in that particular year. As discussed
22 in DEIS Chapters 3 and 4, there are often a variety of biological reasons why flow
23 modifications may not be beneficial or even desirable. For example, there is no need to
24 perform an ESH-creation release if sufficient ESH already exists as the result of
25 previous hydrological conditions or mechanical construction.
- 26 The proposed modification is not strictly one introduced for the benefit of HCs, but
27 since it has an important direct effect on HCs it is reiterated here for clarity and
28 emphasis. The definition of significant benefit would need to be determined, but the
29 issues involved are discussed in Chapters 3 and 4.
- 30 5.8.3.2 *Low storage release considerations*
- 31 Some HCs, including irrigation and recreation in the upper three reservoirs, have NED
32 benefits that are closely and positively correlated to system storage. Annual average
33 system storage over the period of record for the DEIS Alternatives is shown in Figure 92.
34

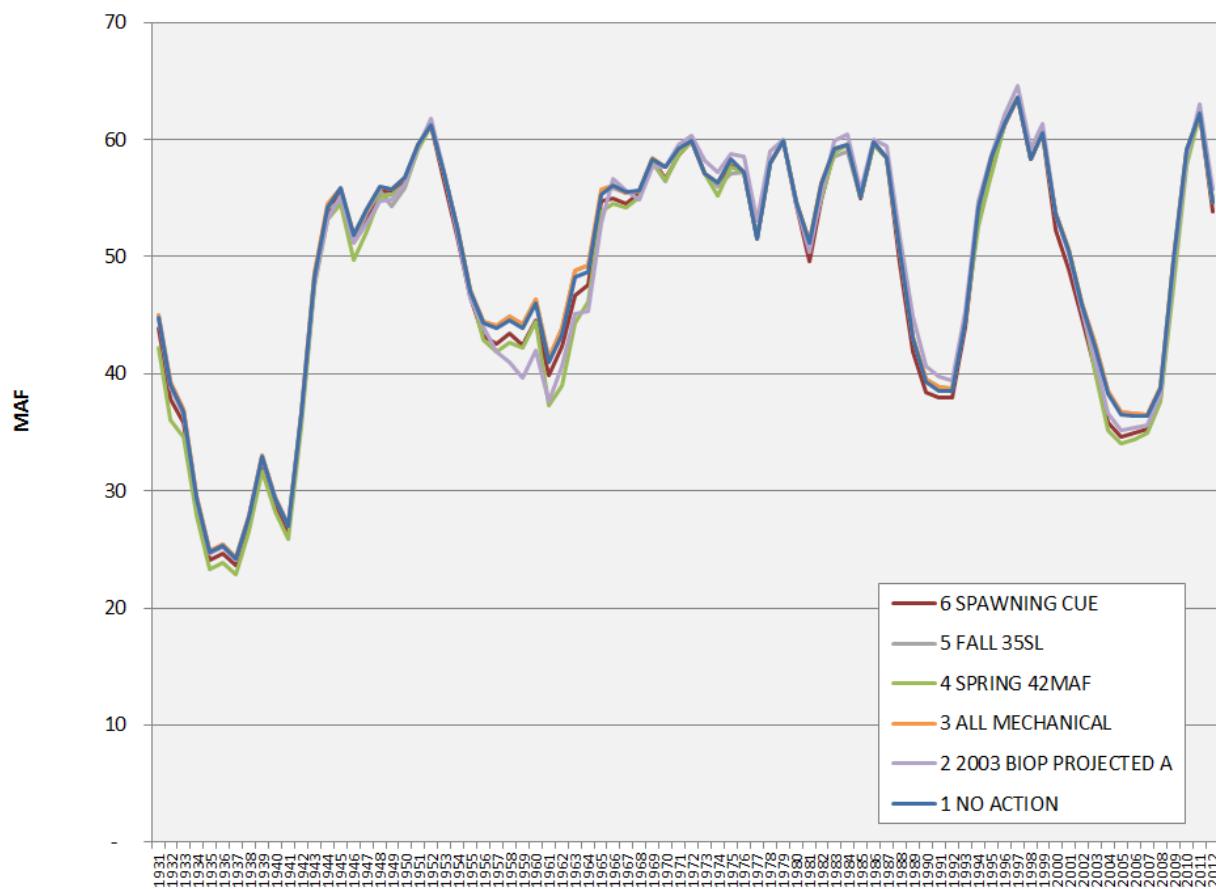

1 For much of the period of record, the storage is aligned across the alternatives. In these
2 years, there is a relatively small difference between the alternatives' performance for
3 irrigation and reservoir recreation. However, there are several periods of time in this
4 period where the storages of the alternatives separate – most noticeably this occurs in
5 the late 1950s and early 1960s, in the early 1990s and in the mid-to-late 2000s.

6 As discussed in EIS Chapter 3, Alternatives 2 and 4 have the most adverse impact to
7 recreation on the reservoirs in the upper basin. Figure 93 shows the change in
8 recreation on the reservoirs in the upper basin NED from No Action for Alternative 4.
9 Comparing Figure 92 and Figure 93, it can be seen that the most negative impacts to
10 upper basin reservoir recreation occur in the same time periods as low storage events, as
11 previously noted. But we can also see that ESH release events (shown as red bars) are
12 not the ones associated with the worst impacts. A similar impact profile can be observed
13 for irrigation.

14 Examination shows that, while not unusually impactful directly, the flow releases
15 sometimes appear to trigger a series of years with negative impacts, e.g. following
16 releases in 1931 (recreation NED data are unavailable for the 1931 release and so cannot
17 be seen in the figure), 1961 and 2003. On investigation, we observe a situation that is
18 common to several HCs that are sensitive to low-system-storage situations:

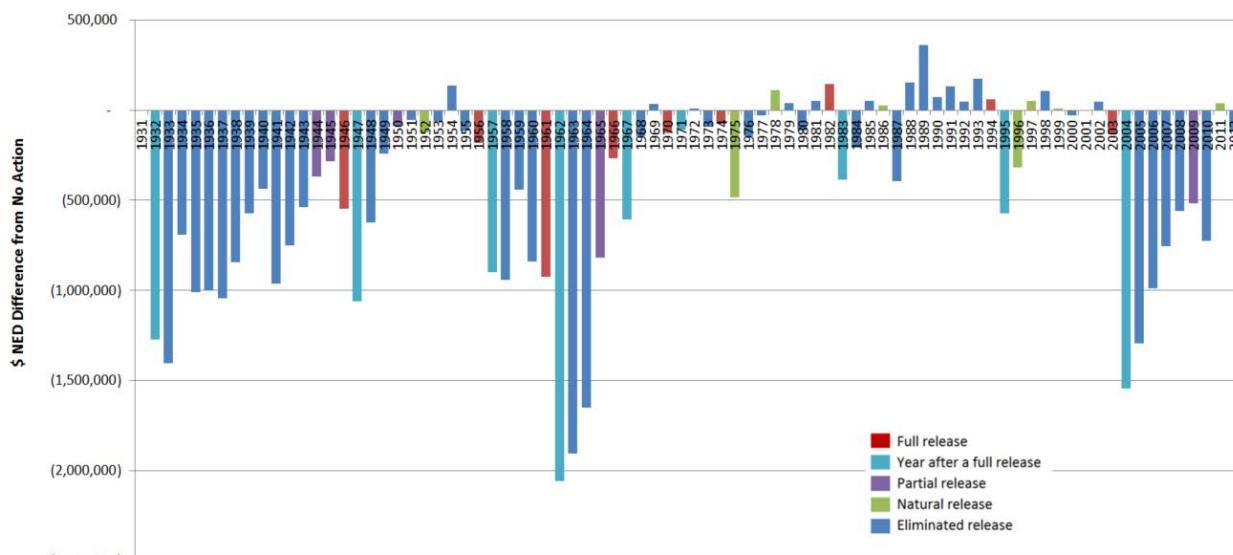

19 It is helpful to explore the reasons why the early 1960s result in unusually high impacts
20 relative to No Action. In data year 1961, both No Action and Alternative 4 are at a system
21 storage that is close to the 42 MAF threshold line (i.e. the minimum storage allowed
22 under Alternative 4 for which ESH flow releases can occur). Under the rules of
23 Alternative 4, an ESH-creation release is permitted in that year. However, subsequent
24 years have low inflows and the system cannot quickly recharge. In the 1962 data year,
25 the previous year's release has forced storage to be lower. In 1963, inflows allow storage
26 and recreation benefits to increase under No Action. However, under Alternative 4 this
27 recovery does not occur in the same way. This sequence of factors caused 1963 to be the
28 single worst difference year for Alternative 4. This series of years appears to be the
29 major single event that drives negative upper river recreation on the reservoirs in the
30 upper basin and irrigation impacts over the period of record, though a similar sequence
31 of events can be seen in the late 2000s.

1

2

3 Figure 92: Annual Average System Storage over the Period of Record for the DEIS Alternatives

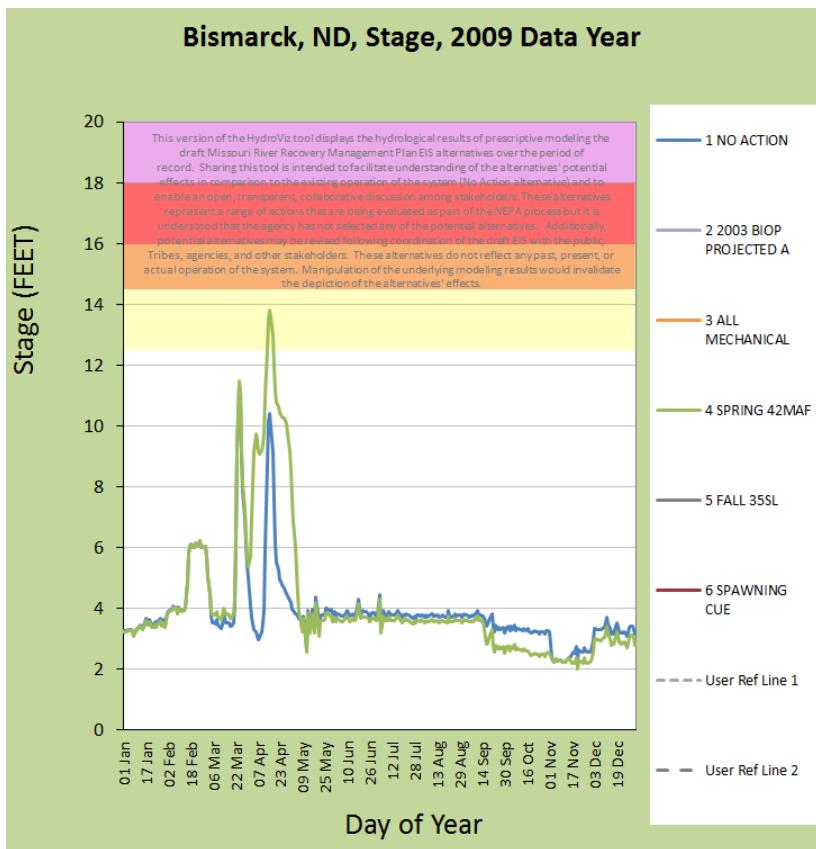

4

5 Figure 93. Upper Recreation NED Difference from No Action by Release Type for Alternative 4.

- 1 To avoid these impacts, several alternative definition modifications might be
2 considered:
- 3 The first could involve changing the storage threshold below which releases may occur.
4 For Alternative 4, this threshold is 42 MAF and for Alternative 2 and 6 the threshold is
5 40 MAF. Alternative 5, which does not appear to be vulnerable to this kind of effect, is
6 defined using navigation storage levels rather than system storage, but it has an
7 approximate equivalent storage threshold of 54 MAF. Increasing the storage thresholds
8 associated with Alternatives 2, 4 or 6 may therefore decrease the likelihood of a 1960s-
9 like sequence of events.
- 10 Increasing the thresholds, however, would have the effect of reducing the frequency of
11 releases, and therefore should be expected to result in less effective results for the ESA
12 species over the long term.
- 13 A second approach might be to leave the thresholds as they are, but to cancel or avoid
14 releases if a second set of circumstances are also present. For example, if storage has
15 been relatively low for a number of years (and close to the storage threshold for a
16 release), absolute adverse impacts to recreation on the reservoirs in the upper basin and
17 irrigation will have accrued. Releasing for species under such circumstances may be
18 expected to further extend or exacerbate the risk period for these HCs and could be
19 reconsidered, particularly if the species requirements are not themselves acute.
- 20 5.8.3.3 *Dry year storage refilling considerations*
- 21 This issue was revealed through an analysis of thermal power impacts in the upper river,
22 but has significance for all intake-sensitive issues in both the upper and lower river.
- 23 A flow release from an alternative by definition discharges a larger quantity of water
24 from a dam than would otherwise have been the case under the No Action alternative in
25 a relatively short period of time. Once discharged, system storage is lower than it would
26 have been without it. To recharge the system storage to its normal desired operating
27 condition, more water must be accumulated in the upper three reservoirs than would
28 have been the case under No Action. Therefore, during this period, there is less water
29 released to the river than would have been the case before. If flows in the river are
30 already low, then the situation could arise where a flow release, once passed, causes
31 river flows to lower below the shut-down intake elevation, reducing power generation
32 and causing increased costs to utilities and power plants.
- 33 An example of this is shown in Figure 94, which shows stage at Bismarck in 2009 for No
34 Action and Alternative 4. In this data year in the upper river, across all alternatives, a

1 relatively high-flow spring transitions into a low-flow summer. In the modelling,
 2 Alternative 4 has a full flow release in this year that leaves system storage at a lower
 3 level for Alternative 4 than would have been the case under No Action. Subsequent
 4 system refilling under Alternative 4 in 2009 during mid-September and October is
 5 therefore occurring against a backdrop of unusually low river flows. This leads to intake
 6 issues associated with this alternative in this year, and a negative impact of tens of
 7 millions of dollars, a substantial contributor to the overall average estimated impact for
 8 this Alternative on this resource area alone.

9
 10 Figure 94. Modelled stage at Bismarck in 2009 under two Alternatives

11 This type of event could be avoided by a number of approaches. Thermal plant and other
 12 sensitive intakes could be reconfigured or replaced to make them less susceptible to low
 13 flows, or definitions of situations governing ESH flow releases could be modified.
 14 Another approach might be to monitor sensitive intake elevation risks and release extra
 15 water from Garrison to ensure they remain functional, with system refilling occurring
 16 later. In the upper river, the USACE's preferred approach to this issue is to evaluate if
 17 the minimum release at Garrison during the fall period is problematic with respect to
 18 water intakes, and to amend it if so. Such a change may or may not be possible within

1 the operational flexibility provided by the Master Manual. Further modelling would be
2 required to fully investigate the system-wide implications of this change.

3 *5.8.3.4 Hot dry summer thermal power considerations*

4 The thermal power plants that use Missouri River water for cooling are subject to state
5 water quality temperature standards. DEIS alternatives that reduce volumetric flowrate
6 in the river during a hot summer period could contribute to higher river temperatures
7 relative to No Action. Low summer flow events under Alternative 2 could cause water
8 quality standards to be exceeded when otherwise they would not have been under No
9 Action.

10 An ERDC Water Temperature Model discussed in DEIS Chapter 3 shows that the low
11 summer flow events as simulated under Alternative 2 increase river temperatures in the
12 lower river when compared to No Action. The economic implications of these events
13 appear to be in the tens of millions of dollars from reduced costs to replace power
14 generation to meet water quality standards and costs to replace lost capacity. However,
15 there are a number of uncertainties in this analysis.

16 USACE would likely work with power plant operators and regulators to use the
17 operational flexibility provided by the Master Manual to avoid shutdown of multiple
18 thermal power plants if this outcome appeared imminent. This would be true under any
19 implemented alternative.

20 Given its heightened risk in this respect, if Alternative 2 were to be implemented,
21 further analysis would be required to confirm that there is sufficient discretion within
22 the Master Manual rules to accommodate this issue and to clarify the system-wide
23 implications of such an operational modification. One important consideration would be
24 that low summer flow operations for birds cannot simply be abandoned once started
25 without the possibility of a sizeable adverse impact on birds that may have taken
26 advantage of the additional habitat provided by the low flow operation.

27 *5.8.3.5 Spring release supplementary flood risk minimization*

28 Modeling suggests that alternatives with spring flow releases appear to have unusually
29 high impacts to flood risk management issues in four data years: 1950, 2009, 1944 and
30 1982. The single largest event relative to No Action occurs with Alternative 4 under 1950
31 data.

32 Figure 94 illustrates the latter case, but the same explanation applies for each of these
33 years. From this figure, we see that the No Action (blue line) sharply increases in April,

1 the result of a sudden inflow from the Heart River. Under Alternative 4 (green line) this
2 year coincides with a flow release that adds additional water on to this natural event.
3 Regular flood avoidance rules do not prevent or discontinue this flow release because
4 the flows rise suddenly *after* the flow release has already been initiated, and because the
5 model does not employ flood checks in Bismarck.

6 As the hydrograph shows, the rapid rate of stage increase in the Bismarck area from the
7 tributary inflow presents a challenge to avoid or mitigate. The Bismarck example has a
8 relatively short lag time between release and impact (Bismarck is about 70 miles
9 downstream of Garrison Dam), but in other locations identified in the modelling where
10 this effect is seen the lag time between flow releases and impacts are longer, further
11 reducing USACE's ability to react in time to avoid impacts. For these reasons, the overall
12 effectiveness of measures to avoid or mitigate the increased flood risk issues associated
13 with spring flow releases is uncertain, and may not be large.

14 If an alternative with a spring flow release were to be pursued, actions that could be
15 undertaken to help avoid or mitigate this situation could include:

- 16 • Increase the use of advanced Quantitative Precipitation Forecasting (QPF)
17 techniques in tributaries and in the river;
- 18 • Increase the use of continuous monitoring of flood stages in potentially affected
19 areas (perhaps in tributaries) in order to more rapidly be alerted to actual flood
20 risks

21 It might be possible for improved weather forecasting efforts along tributaries like the
22 Heart River to provide more advance warning about such events. This could combine an
23 analysis of snowpack conditions as well as local precipitation events. Additionally, in the
24 modelling, flow releases are not stopped when flooding occurs in Bismarck because
25 there are no operational flood checks there. In actual operation, it is unlikely that a flow
26 release for endangered species would continue during a flood event.

27 A further issue affecting spring flood risk concerns the presence of ice in the river. Ice
28 increases flood risk in the channel by reducing its effective capacity. Modelling cannot
29 predict which years have ice. In reality, the USACE would not release additional water
30 into the channel for species flows if ice were present.

31 5.8.3.6 *Fall release supplementary flood risk minimization*

32 A parallel situation to the spring release occurs with the fall release associated with
33 Alternative 5, though to a considerably lesser degree because inflows in the period of

1 release are less volatile than in the spring, and because Alternative 5 has a lower
2 expected number of releases than Alternative 4 due to its higher minimum release
3 threshold. Nevertheless, there are some examples of rapid inflows from tributaries into
4 the Missouri River resulting in an increase in flood risk during an Alternative 5 flow
5 release (e.g. using 1982 data for the lower river – a partial release that is cut short by
6 existing flood control rules, but not before incremental damage has accrued).

7 As with the spring flows, it is possible that if Alternative 5 were to be implemented,
8 increased use of advanced Quantitative Precipitation Forecasting (QPF) techniques in
9 tributaries that have the highest likelihood of creating this kind of problem in the
10 October to November release window might help avoid or mitigate this issue to some
11 degree, though the effectiveness of this action would need to be studied. As with the
12 spring release, the inherently sudden nature of these inflows combined with river travel
13 time may limit the Corps' ability to respond to such situations.

14 5.8.3.7 *Fall release agriculture co-ordination*

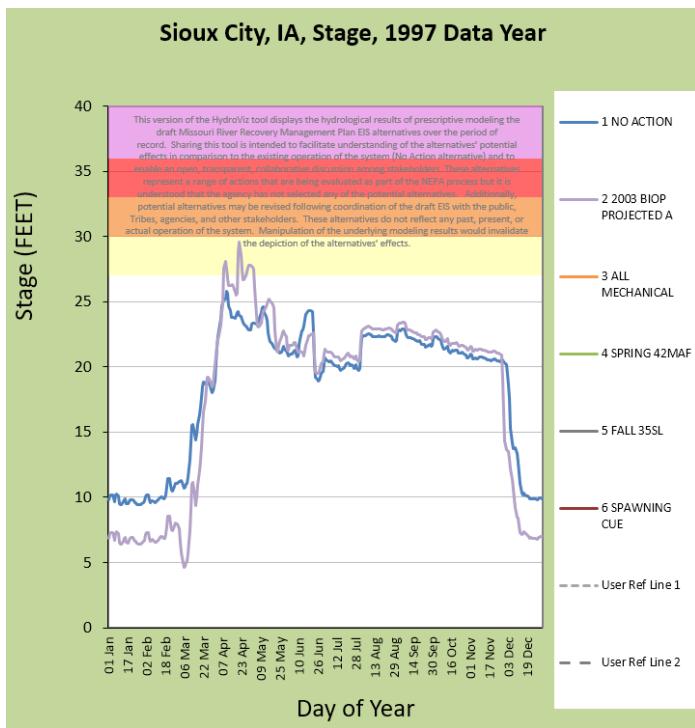

15 If Alternative 5 were to be implemented, The USACE may wish to coordinate with
16 farmers around the precise timing of the fall release, should one be planned. In the
17 current modeling, this alternative's flow release is timed to start as late in the year as
18 possible (to avoid impact to farming) while still allowing for a 5.5 week release with a
19 low probability of complications from ice formation at the end of that period. As
20 previously established, it would need to be explicitly stated that in the event of an early
21 ice-up of the river towards the end of a fall release, Alternative 5's flow release would
22 have to be abandoned for flood risk management issues.

23 However, there may be some scope for discussion on the precise timing of this release
24 that investigates further and more explicitly the balance between a later start to the
25 release and the latest time in the year for which the flow release could be stopped for ice
26 reasons. For example, in some years it may be possible to extend the period of release if
27 ice concerns are clearly not an imminent concern that year, creating more ESH.
28 Conversely, perhaps a later start to the release could be acceptable in some years to
29 avoid agriculture impacts if sufficient ESH has been created before the completion of 5.5
30 weeks.

31 5.8.3.8 *Winter low-flow avoidance*

32 Under Alternative 2, a maximum winter release of 16 kcfs is prescribed, which is lower
33 than that prescribed for No Action. Low flows over the winter are important for all
34 alternatives to avoid flooding risk associated with ice. However, the intent of this

- 1 additional specification for Alternative 2 is to increase the probability of high storage in
 2 the system in spring to allow for a more effective spring pulse for pallid sturgeon.
- 3 There are a number of downsides with this specification of alternative 2, however. Some
 4 intake-based HCs suffer disproportionately from the reduced stage during this period.
- 5 Additionally, the USACE is forced then to release this extra water in the spring in order
 6 to meet the storage targets at the onset of the spring season. In the modelling, this
 7 additional release of water, in combination with higher than average inflows, can lead to
 8 increased flood risk (Figure 95).

9

10 Figure 95. Stage at Sioux City using 1997 data for Alternatives 1 and 4

11 In some respects, the increased flood risk shown in this situation in the modelling is
 12 higher than would actually occur and is a function of the model being aggressive in
 13 meeting its ideal storage targets in spring. However, the underlying dynamic is real and
 14 if Alternative 2 were to be implemented the requirement for 16kcfs during the winter
 15 should be re-examined.

16 5.8.3.9 Managing unexpected impacts to HCs

17 Provisions for managing unanticipated impacts to species and HCs are integrated into
 18 the governance structure detailed in AM Chapter 2. In some respects, USACE water

- 1 management already uses discretion, given it by law to operate the System for its eight
 - 2 authorized purposes, in modifying operations within the boundaries set by the Master
 - 3 Manual to accommodate emerging HC issues. During the implementation of this Plan,
 - 4 the HC Group would be free to raise such issues to the Management Team level during
 - 5 the regular annual planning cycle and any modifications to operations for the
 - 6 approaching years would be considered at that point.
-
- 7 The case of a sudden, acute HC issue that might preclude the use of a flow release in
 - 8 season (were an alternative to be implemented that contained one) would be raised
 - 9 directly at the Management Team level at the discretion of the USACE.

61 **Data Acquisition, Management, Reporting and** 2 **Communications**

3 **6.1 Principles and practices underpinning monitoring and evaluation, data** 4 **management, and effective communications**

5 This Chapter outlines a set of principles for developing and implementing a monitoring
6 and evaluation (M&E) strategy. Underpinning these principles is recognition that the
7 activities in the AM Plan are intended to increase knowledge of how to best protect and
8 recover listed species, while concurrently meeting authorized purposes and minimizing
9 undesirable effects. Thus, M&E is a crucial post-implementation activity, and many of
10 the activities are optimized for the twin objectives of learning and ecological
11 effectiveness (within HC constraints). The objectives will shift over time and, as the
12 underpinning science and species needs are better understood, actions will focus more
13 strongly on ecological effectiveness, with learning as a secondary benefit.

14 The principles outlined in this Chapter are drawn from multiple sources designed to
15 ensure the development and iterative evolution of an effective M&E strategy:

- 16 1. The Data Quality Objectives process (DQO; EPA 2006), developed by the U.S.
17 EPA to guide development and evaluation of alternative M&E designs to make
18 decisions, is a collection of qualitative and quantitative statements that help to
19 clarify program objectives, define appropriate types of data to collect/analyze,
20 and specify tolerable limits on potential decision errors. This provides a basis for
21 establishing the quality and quantity of data needed to support decisions.
- 22 2. Applications of the DQO process and evolutionary development of M&E
23 strategies in various ecosystem restoration, environmental monitoring and
24 species recovery programs provided relevant examples. These include the U.S.
25 EPA's Environmental Monitoring and Evaluation Project (Barber 1994), the
26 Columbia Basin's Collaborative System-wide Monitoring and Evaluation Project
27 (CSMEP 2007), other M&E strategies for the Columbia Basin (Hillman 2006),
28 the Comprehensive Everglades Restoration Program (CERP) Monitoring and
29 Assessment Plan (MAP; RECOVER 2009) and the associated Quality Assurance
30 Systems Requirements (QASR; RECOVER 2004), the Integrated Assessment
31 Program for the Trinity River Restoration Program (TRRP and ESSA 2009), and
32 the Platte River Recovery Implementation Program (PRRIP 2014).
- 33 3. Expert advice from scientists familiar with the M&E challenges specific to the
34 Missouri River and other large-scale ecosystems were instrumental.

1 Effective M&E requires attention to detail organized around each of the steps in the AM
2 cycle (see Figure 5):

- 3 1. **Plan/Design:** Assess the problem, identify priority decisions, questions,
4 hypotheses and indicators, and design the M&E strategy for each hypothesis and
5 management decision (this strategy guides the remaining steps)
- 6 2. **Implement** management actions
- 7 3. **Monitor** the ecosystem, its species and selected metrics for human considerations,
8 and collect appropriate data
- 9 4. **Evaluate** monitoring data and determine the implications of the data for priority
10 decisions, hypotheses, and the original M&E strategy
- 11 5. **Decide** whether or not to adjust actions, hypotheses and/or the M&E strategy.

12 In addition to the principles summarized in this section, issues of scale are discussed
13 and the term “actionable science” is defined and discussed in the context of the MRRP.
14 The agencies are committed to a collaborative process for developing and implementing
15 the MRRP, so an open data-management strategy, transparent decision-making, and
16 good reporting and communications are central to success. Section 6.2 provides a
17 summary of monitoring and data acquisition for the system and the listed species.
18 Section 6.3 outlines the approach for addressing “new information”, Section 6.3
19 discusses the needed data management and communications, and quality assessment
20 and quality assurance processes are discussed in Section 6.4.

21 *6.1.1.1 M&E Principles for the Plan/Design step of the AM Cycle*

22 The Plan/Design step (Step 1) for the MRRP AM Plan was addressed through the EA
23 and the MRRMP. An M&E design describes the combination of logical, statistical,
24 field/logistical and cost strategies to answering one or more management questions that
25 feed into a management decision. Components of an M&E strategy can include
26 (modified from Hillman 2004):

- 27 a) a “statistical” design, which provides the logical structure for testing
28 hypotheses, using spatial and temporal contrasts, and identifying the
29 minimum requirements for implementation monitoring, process /
30 effectiveness monitoring and population monitoring;
- 31 b) a “sampling” design which describes the process for selecting sampling sites
32 and sampling times;
- 33 c) a “measurement” design outlining the specific performance measures and the
34 protocols used to monitor them at the chosen sites and times; and
- 35 d) a “response” design that explains how the monitoring data will be analyzed to
36 make inferences in the AM Evaluate step.

1 The plan/design step is the most critical part of the AM cycle for development of M&E
2 strategies, since it must anticipate all of the steps to follow. Many of the research
3 activities described for pallid sturgeon under Level 1 will help with the design of M&E
4 strategies. The following principles, drawn directly from the DQO process described in
5 EPA (2006), set the foundation for effective M&E strategies in Step 1:

- 6 1. *State the problem* – define the problem based on a conceptual model, identify
7 priority hypotheses and indicators related to management actions
- 8 2. *Identify the decision* – state the decision to be made, the actions to be
9 undertaken, the key questions to be answered. Clarify the wording of those
10 questions until they can be answered positively or negatively, specifying location,
11 timing, target populations, relative comparisons and other attributes.
- 12 3. *Identify inputs to the decision* – decision criteria, key metrics. Metrics ideally
13 should have: a high signal to noise ratio (not too variable in space or time), have
14 direct relevance to decision criteria, have high cost effectiveness, be ecologically
15 responsive (i.e., do not have a long lag in response to changing conditions), are
16 unambiguously interpretable, have minimal environmental impact and have a
17 clearly defined measurement protocol. Evaluating metrics against these and
18 other criteria (see Table 5-1 in Barber 1994) will help to refine the list of key
19 metrics.
- 20 4. *Define the study boundaries* – must be sufficiently large to encompass the
21 distribution of management actions over space and time, and the potential
22 impacts of those actions
- 23 5. *Develop a clear path from data to decisions* - Effective M&E strategies have a
24 defensible reason for all information that will be collected, which either directly
25 or indirectly have implications for management decisions.
- 26 6. *Develop “if-then” decision rules* – Define a statistical parameter of interest for
27 each metric (e.g., median survival rate or abundance for species; flow, stage or
28 reservoir level thresholds for impacts on HCs), and a set of positive or negative
29 outcomes for each priority question, which can be melded into “if-then” decision
30 rules with biologically or socioeconomically significant effect sizes. Such decision
31 rules may involve multiple questions and metrics, as described for pallid sturgeon
32 (see section 4.6).
- 33 7. *Specify limits on decision errors* – Define precision requirements for decisions
34 and acceptable limits for decision errors (e.g. lower precision is required to
35 determine whether pallid sturgeon spawning occurs in a given location than to
36 determine the survival rate from eggs to age-1). False positives for species'
37 metrics (e.g., falsely concluding that an action was effective in helping listed
38 species when in fact it wasn't) could lead to implementation of ineffective actions

1 in place of effective actions, potentially resulting in negative economic and
2 ecological impacts. False negatives (e.g., falsely concluding that an action had no
3 effect on a population, when in fact it had a positive effect) could lead to negative
4 ecological effects if effective actions are stopped. False positives for HC metrics
5 (e.g., falsely concluding that a management action negatively affected HCs when
6 in fact such impacts were unrelated to the action), might also lead to unnecessary
7 reduction or cessation of an ecologically effective action. False negatives for HC
8 metrics (e.g., concluding that an action had no effect on HCs when in fact it had a
9 negative impact) could have undesirable social and economic effects.

- 10 8. *Optimize the M&E design for obtaining data* – Develop and evaluate different
11 M&E designs, examining their ability to meet the required levels of precision at
12 an acceptable cost. Optimization of the design may involve considerable work at
13 Level 1 and Level 2, including various efforts to refine methods before finalizing
14 the design, which leads to the following principles. Monitoring of HC metrics
15 should follow a similar process.
- 16 a. Ensure that important time series are maintained if monitoring protocols
17 are being improved.
- 18 b. Use past data and possibly intensive pilot sampling to gain insight into
19 spatial and temporal variability of key metrics (e.g., relative abundance of
20 age-0 pallid and shovelnose sturgeon within different habitat types), and
21 how relative abundance varies over time and river conditions.
- 22 c. Perform statistical power analyses to determine how false positives and
23 false negatives vary with sampling effort, number of treatment
24 (management action) and reference sites, the staging of implementation of
25 management actions, and the number of years of monitoring before and
26 after the action is implemented (see Appendix E for an example of
27 statistical power analyses applied to IRCS).
- 28 d. Allow for an adjustment period with new monitoring needs, and use pilot
29 approaches to discover bugs and solve initial problems.
- 30 e. Complete laboratory and mesocosm work at Level 1 to define biological
31 effect sizes of interest, clarify mechanisms of impact, assess measurement
32 errors and refine monitoring protocols.
- 33 f. Complete modelling studies at Level 1 to simulate different M&E
34 strategies.

1 6.1.1.2 *M&E Principles for the Implement Stage of the AM Cycle*

2 The implementation of experimental management actions at Level 2 provides an
3 opportunity to both further species objectives and to refine M&E strategies:

- 4 1. Use L2 management experiments to benefit listed species and test M&E
5 strategies, examining their ability to reliably evaluate the effectiveness of
6 management actions, and their effects on selected HC metrics.
- 7 2. In designing L2 management experiments, seek to maximize spatial and
8 temporal contrasts within the constraints of both feasibility and authorized
9 purposes.
- 10 3. Ensure that L2 management experiments have a low risk of negative effects on
11 listed species (e.g., use hatchery fish in a manner which does not affect stocking
12 programs) and HCs (e.g., implement habitat restoration actions in locations and
13 forms which maximize ecological effectiveness and minimize impacts on HCs).

14

15 6.1.1.3 *M&E Principles for the Monitor step of the AM Cycle*

16 Monitoring (Step 3) includes the following considerations for metrics and data
17 collection:

- 18 1. Ensure adequate training of field crews on the sampling and measurement design
19 (the why, in addition to the where, when, how and who).
- 20 2. Apply the sampling design and measurement design as laid out in the Design
21 step, and document any deviations from that design.
- 22 3. Where there are insufficient field data to estimate measurement error, do
23 replicate tests of monitoring (e.g., the same field crew sampling the same location
24 on the same day; multiple crews sampling the same location on the same day)
- 25 4. Collect information on key covariates which might affect sampled values (e.g.,
26 turbidity, velocity, temperature) and be helpful in subsequent Evaluate step.
- 27 5. Ensure that the data are stored in a reliable data storage and management
28 system, and promptly reviewed for data quality (section 6.4).
- 29 6. Apply good principles of data management (section 6.3.2.2).

30

31 6.1.1.4 *M&E Principles for the Evaluate step of the AM Cycle*

32 Evaluation of monitoring data (Step 4) includes determining the implications for
33 priority decisions, hypotheses, and the original M&E strategy. Important principles
34 include:

- 1 1. Apply the statistical and response designs laid out in the Design step of the AM
2 cycle, and test out whether the key assumptions of the design have been fulfilled.
- 3 2. Synthesize multiple metrics and multiple lines of evidence in decision-focused
4 assessments.
- 5 3. As problems are detected in analyzing the data, develop and evaluate possible
6 revisions to the sampling and measurement designs.

7

8 *6.1.1.5 M&E Principles for the Adjust Step of the AM Cycle*

9 An important component of the Decide step (Step 5) of the AM cycle involves
10 determination of whether or how to adjust actions or decision, with the following
11 important guidelines:

- 12 1. Test pilot data evaluations (and the decision criteria developed in AM step 2)
13 with managers to ensure that the M&E strategy is providing the appropriate
14 inputs to decisions, in terms of form and content.
- 15 2. If changes to existing M&E protocols are considered, particularly those with
16 implications for trend analyses, ensure that there is a sufficient period of overlap
17 of the old and new methods to permit cross-comparisons.
- 18 3. Ensure that changes being considered to management actions are harmonized
19 with the overall experimental designs and objectives for all system components.

20 **6.1.2 Issues of scale**

21 The effects from implementing the MRRP projects must be monitored at both system-
22 wide and local scales. The ISP is responsible for the design and implementation of
23 system-wide monitoring of birds and fish, and will work with the individual MRRP
24 PDTs for design and implementation of monitoring to determine local effects and
25 project performance. To guide implementation of the system-wide program, the AM
26 Team is developing the MRRP Monitoring and Assessment Plan (MAP), an associated
27 Quality Assurance Requirements (QAR), and a QA/QC document. Materials addressing
28 monitoring and assessment that comprise the MAP are presently included in several
29 chapters, appendices and attachments to the AM Plan (see particularly chapters 3, 4 and
30 5; and appendices D, E, G, H and I). These materials and associated QAR will be
31 integrated together into the complete MAP as part of the implementation of the AM
32 Plan. The MAP and the individual project monitoring plans will be closely coordinated
33 to ensure that measures and targets selected by the project teams are consistent with
34 system-wide measures and that duplication of effort is effectively minimized.

1 Monitoring at the project scale should ensure appropriate temporal and spatial coverage
2 of monitoring parameters, which may require filling gaps in the MAP monitoring effort
3 or adding additional project-level parameters not included in the MAP, particularly for
4 monitoring action effectiveness at local scales.

5 **6.1.3 Actionable science**

6 For the MRRP to meet its objectives and work effectively with its partners and
7 stakeholders, it is important that decisions be based on the best available science (see
8 Murphy and Weiland 2011, 2016 for a definition). The science is currently challenged by
9 a number of underpinning uncertainties (see Jacobson et al. 2015, Buenau, et al. 2016,
10 Fischenich et al. 2016; and see Sections 3.1.2.5 and 4.1.2.5), and the AMP includes a
11 number of studies aimed at addressing these challenges. Meanwhile, implementation
12 decisions are necessary in order to meet the requirements of the ESA and avoid
13 jeopardizing the listed species.

14 The term “actionable science,” was coined by the Department of Interior’s Advisory
15 Committee on Climate Change and Natural Resource Science (ACCCNRS 2015) and it
16 serves as a useful concept for guiding the information necessary to support MRRP
17 decision-making while fulfilling the best-available science mandate. Actionable science
18 provides data, analyses, projections, or tools that can support decisions regarding
19 management of the risks and impacts of operations on the Missouri River. Ideally co-
20 produced by scientists and decision makers, actionable science creates rigorous and
21 accessible products to meet the needs of stakeholders.

22 The following principles, adapted from ACCCNRS 2015, are presented to guide efforts
23 for producing actionable science and are entirely consistent with the principles for
24 monitoring and evaluation described in section 6.1:

- 25 • Scientists, decision makers and stakeholders working in concert are more likely to
26 arrive at actionable science than scientists acting alone.
- 27 • Start with a decision that needs to be made. Research needs are rarely precisely
28 known (and seldom clearly specified) in advance, so must be identified
29 collaboratively and iteratively.
- 30 • Give priority to processes and outcomes over products, and use the process to build
31 connections across disciplines and organizations, and among scientists, decision
32 makers, and stakeholders.
- 33 • Periodically evaluate the utility of products and processes, and the ability to take
34 actions based on the science developed by the program. Use the lessons learned to
35 adjust products and processes as needed, and to refine the definition of “actionable”
36 based on evolving views of risk.

1 This approach recognizes that actionable science is not only actionable information, but
2 also includes longer-term processes and relationship building to help ensure the
3 appropriate use of that information. Time and resources will be required to develop and
4 maintain interpersonal interactions among scientists, decision makers, stakeholders and
5 other users of the scientific information. Deploying these services efficiently and
6 effectively also requires building connections across disciplines, and among the
7 organizations engaged in the effort. The budgets for the program and individual
8 projects, project evaluations, and staff incentives and evaluations should reflect
9 commitment to this need.

10

11 **6.2 Monitoring and data acquisition**

12 The MRRP Monitoring and Assessment Plan (MAP) is the primary guide for evaluating
13 the performance of the MRRP. The MAP is an integrated system-wide monitoring and
14 assessment plan that: (1) provides a framework that supports measurements of the
15 responses of habitats, species and human considerations at both project and system-
16 widescales, to determine how well MRRP is achieving its goals and objectives; (2) helps
17 identify and prevent unintended adverse outcomes
18 from management actions; and (3) supports and
19 enables AM for updating and improving the Plan,
20 as well as management actions, when needed. The
21 scientific and technical information in the MAP is
22 organized in such a way as to facilitate status and
23 performance assessments and report these findings
24 in annual system status reports.

25 The MAP is structured around the conceptual
26 ecological models (CEMs), which are organized by
27 species, but also provides a framework for system-
28 wide monitoring and assessment for the MRRP.

29 Implementation of the MAP builds on trends
30 relative to reference conditions and baselines established for the MRRP to detect change
31 including unexpected responses of the ecosystem, and address not only “what” is
32 happening (e.g., status and trends) but “why” it is occurring (e.g., stressors-response
33 functions), which is essential for implementing AM. Monitoring designs and protocols
34 to assess the effectiveness of specific management actions are tailored to those actions,
35 as described in chapters 3, 4 and 5, as well as in Appendix E (for IRCs).

Note: Materials addressing monitoring and assessment are presently distributed among chapters 3, 4 and 5 and appendices D, E, G, H and I to the AM Plan. We refer to these collectively herein as the Monitoring and Assessment Plan (MAP). These materials, and associated Quality Assurance Requirements (QAR) will be integrated into the MAP as part of the implementation of the AM Plan.

1 Data acquisition practices for individual projects will follow the overall monitoring and
2 evaluation strategy designed for the AM program. Methods of acquiring field data need
3 to be fully integrated with the overall monitoring and evaluation strategy for each
4 component of the AMP, to ensure that, to the extent budget and field conditions permit,
5 necessary data are acquired, receive QA/QC reviews, and are entered into a secure data
6 management system with all associated metadata, as described in section 6.3. The
7 specific objectives and approaches associated with individual projects will likely
8 necessitate

9 **6.2.1 Pallid sturgeon monitoring data acquisition and analysis approach**

10 Pallid sturgeon monitoring data have been collected by multiple teams from several
11 state and federal agencies who have been involved with the MRRP since its inception.
12 This approach has been used for both the Pallid Sturgeon Population Assessment
13 Program and the Habitat Assessment and Monitoring Program. HAMP and PSPAP
14 monitoring coordinators (USACE) manage contracts with partners, coordinate
15 monitoring activities, work with monitoring teams to adjust monitoring efforts if
16 needed, and assist with data analysis and reporting. See Appendix D for a review of
17 current PSPAP guidance and a proposed substantial revision to the current protocols for
18 population monitoring. Other data collection protocols specific to evaluating the
19 effectiveness of Interception and Rearing Complexes are summarized in Appendix E.

20 This multi-team approach has several advantages. Long-term monitoring efforts benefit
21 from a consistent approach and sustained expertise. Substantial pallid sturgeon
22 expertise has been developed within these agencies and long-term involvement of these
23 partners has resulted in needed consistency. Since the missions of these partner
24 agencies overlap with the MRRP objectives, these partnerships help ensure that MRRP
25 activities are closely coordinated with similar and potentially beneficial actions of
26 partner agencies. Finally, inclusion of multiple partners in monitoring efforts helps
27 offset the bias, perceived or real, within any one partner agency, including the USACE.

28 It is vitally important that fish monitoring crews understand the key hypotheses to be
29 tested, the overall monitoring and evaluation strategy, and the reasons for the specific
30 details incorporated into fish monitoring protocols. Understanding the ‘why’ of a
31 monitoring and evaluation program will help to ensure that the ‘what’, ‘where’, ‘when’
32 and ‘how’ are correctly implemented. This deeper understanding by field crews will also
33 catalyze communications between field crews and Technical Team members regarding
34 field observations which may be particularly relevant to the existing set of big questions
35 and hypotheses, as well as potentially suggesting other factors to be considered (e.g.,
36 potential predators or competitors to pallid sturgeon that frequently appear in the same
37 places and times as various life stages of pallid sturgeon).

1 Historically, fish monitoring crews have had little involvement in subsequent data
2 analyses. Some partners have the necessary expertise to assist in these analyses,
3 however, and because analyses will be identified in advance through the AM Plan, some
4 of these analyses (if appropriate to the expertise of contractors) can be included in
5 monitoring contracts, framed around specific hypotheses and questions from the AM
6 Plan. This will allow the MRRP to capitalize on the expertise of partners (i.e.,
7 providing key contributions to the Technical Team) while focusing their work in the
8 non-sampling seasons on the most productive efforts. In the past, the limited off-season
9 analyses which were conducted by individual partners have been uncoordinated and
10 often not focused on the most important information needs of the MRRP. Involvement
11 of monitoring crews in conducting pre-defined analyses will provide a cost-effective
12 means to ensure timely data analysis. In addition, the PSPAP and HAMP coordinators'
13 duties will be redirected to allow more focus on data analyses and reporting.

14 **6.2.2 Bird monitoring data acquisition and analysis approach**

15 Bird monitoring data are currently collected by USACE staff with a heavy reliance on
16 part-time summer employees. This approach works well for the bird monitoring needs
17 as it allows for a high level of staffing during the season (May-August) when the birds
18 are on the Missouri River. This approach also offers potential to adjust staffing levels
19 relatively quickly based on system conditions. For example, a high water year may
20 significantly reduce the area to sample and temporary staffing levels can easily be
21 adjusted. A disadvantage of this approach is the inexperience and annual turnover of
22 many of the bird monitoring staff. This is a challenge that has been identified and is
23 being addressed in order to ensure the needed consistency and quality of data collection.
24 For example, additional oversight and field assistance by roaming veteran staff in 2015
25 has helped to increase consistency among crews. Recent reviews of the strengths and
26 weaknesses of alternative methods for monitoring key bird metrics (Schwarz and Porter
27 2016) provide a basis for considering possible improvements to existing monitoring
28 protocols. Staffing requirements will depend on what bird monitoring protocol is
29 selected (see section 3.3.3 and Appendix G for a discussion of bird monitoring
30 protocols).

31 Analyses of bird monitoring data are performed annually by the USACE bird monitoring
32 coordinator including trend analyses and take reporting. Utilizing a full-time bird
33 monitoring coordinator to lead these analyses ensures consistency, commitment, and
34 the necessary close communication with USACE water management.

1 **6.2.3 System status and HC data acquisition and analysis**

2 System status refers to conditions of the reservoir system, riverine segments, and
3 affected resources. Status measures include primary measures such as tributary
4 inflows, reservoir storage levels, outflows (discharges and stages), channel condition,
5 sediment transport, and water quality parameters. Status measures can also be usefully
6 extended to secondary measures of system resources, such as power production, habitat
7 availability, water supply, navigation support, flooding and other HC metrics. The
8 reasons for monitoring system status include:

- 9 1. Information is needed to guide operational decisions. For example, reservoir
10 releases and downstream stages are needed to evaluate, manage and minimize
11 downstream flooding, a key concern to stakeholders.
- 12 2. Information is needed to assess AM Plan components. For example, reservoir
13 releases, stages, and discharges are needed to evaluate piping plover and pallid
14 sturgeon habitat availability.
- 15 3. Information is needed to assess effects of AM Plan components on human
16 considerations. For example, river stages, sediment transport and state of interior
17 drainage are needed to evaluate effects of flow releases and other actions (e.g.,
18 habitat creation) on agricultural production.
- 19 4. Information is desired to understand unanticipated changes in the river and
20 associated resources. For example, low reservoir releases, high air and water
21 temperatures, and local thunderstorms may generate local inflows with high
22 nutrient concentrations, resulting in low dissolved oxygen and fish kills. As
23 discussed in Chapter 4, low oxygen concentrations in the bottom waters of Fort
24 Peck Lake and Lake Sakakawea reservoirs cause mortality of pallid sturgeon
25 embryos (Guy et al. 2015).

26 Investments in monitoring for these types of information will certainly vary by category.
27 Category 1 is essential to Missouri River System operations and continued investment is
28 highly justified. Categories 2 and 3 are additive to category 1, and are central to AM of
29 the habitats and species; return on investment for monitoring this information is
30 considered high but may be implemented variably depending on affected resources.
31 Information relating reservoir releases, river stage, and water intake efficiencies, for
32 example, may be prioritized for category 3. Which human-consideration metrics will be
33 included in system status monitoring will be based on results of the impacts analysis
34 being conducted for the EIS, the preferred alternative, and the range of factors discussed
35 in Section 5.5. For years in which flow actions are not implemented (all years under

1 alternative 3 in the EIS), a major focus of HC monitoring is likely to be in the immediate
2 vicinity and downstream of projects to construct ESH, IRCs or spawning habitat.
3 Monitoring priorities and strategies will be discussed and designed collaboratively with
4 stakeholders as part of the AM Plan development process, and periodically reviewed
5 following the processes laid out in Chapter 2.

6 Category 4 relates in large part to water-quality data and return on investment to the
7 MRRP is not as clear as the other categories, except in cases where they directly
8 influence MRRP decisions (e.g., the extent of anoxic waters in the bottom waters of Lake
9 Sakakawea has important implications for decisions on Upper Missouri pallid sturgeon
10 actions, as discussed in the summary of the EA in section 4.1.2). Water-quality stressors
11 result from combinations of USACE management actions and from widespread actions
12 beyond USACE authority. Examples include point discharges from municipal and
13 industrial water-treatment facilities and non-point discharges of nutrients, sediment,
14 and bacteria from basin agricultural sources. Concerns about water quality are
15 therefore shared among many agencies and authorities. Although it is reasonable to
16 expect all riverine biota to be affected to some extent by water quality, specific water-
17 quality stressors to piping plovers and pallid sturgeon did not emerge as dominant
18 hypotheses from the EA, except for the issue discussed above for Lake Sakakawea
19 oxygen concentrations. Therefore, no clear link between water quality and AM of the
20 two species presently exists. Some level of foundational water quality monitoring may
21 be justified to the MRRP to avoid risk and to prepare for unanticipated conditions, and
22 the USACE plans to work with other Federal and State agencies and other stakeholders
23 to seek a cost-effective, collaborative ambient water quality monitoring program to
24 assess status and trends of parameters that may affect habitats and socio-economic
25 values.

26 Analysis of the system status information will be performed annually by the Technical
27 Team, and will include trends analyses and model validation results along with other
28 data related to system status. This information will be presented at the AM Science and
29 AM Workshop and included in the annual report.

30 **6.2.4 Research data acquisition**

31 Many research efforts will be relatively short term (i.e. 1 to 3 years). For most research,
32 the MRRP Integrated Science Program will utilize a competitive proposal solicitation
33 process open to government agencies, public sector contractors, and universities
34 through an open Request for Proposals. Research projects will be selected on the basis
35 of their support of MRRP AM needs, demonstrated capabilities of proposers, the value
36 of information, and cost effectiveness. Selections will be made by the USACE but
37 informed by proposal reviews from an independent panel. The selected researcher will

1 then become the principal investigator for that particular research project. Solicitation
2 of proposals should occur far enough in advance so that information on potential costs
3 and timelines is available as budgets are being developed. The Integrated Science
4 Program is committed to the use of peer review and will refine peer review guidelines
5 for reviewing research proposals, publications, and other products or deliverables.

6 If research or monitoring efforts have little staff turnover or outside influence, they can
7 suffer from a narrow perspective and a tendency to not question the current paradigm
8 while missing key lessons learned in other systems. These challenges can be overcome
9 in the AMP with appropriate independent reviews, interdisciplinary feedback at annual
10 AMP science meetings and workshops, a competitive research proposal process, and
11 increased room for scientific influence from outside the basin (e.g., a defined role for
12 Federal Recovery Teams).

13 Many Level 1 science components for pallid sturgeon will be implemented concurrently,
14 subject to budget constraints, which will require an intensive effort to organize the
15 science plan, coordinate multiple science components, and communicate interim
16 findings to all parties.

17 **6.2.5 New Information**

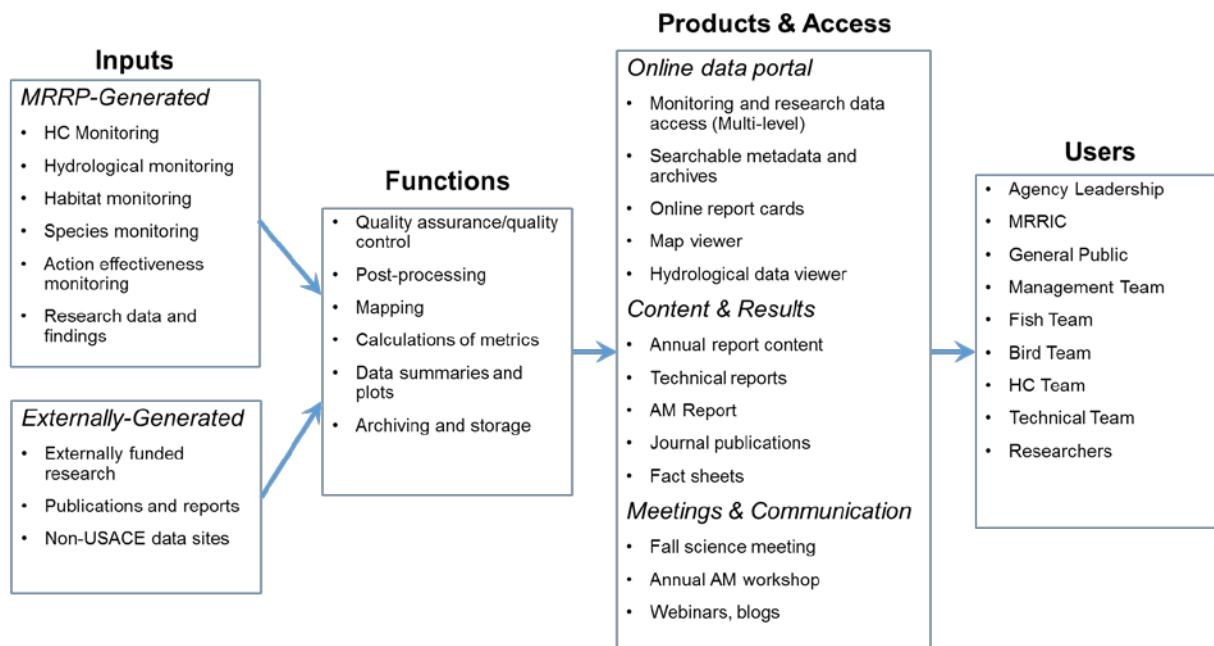

18 New or newly introduced information related to the listed species life history, their
19 habitats, or system response requires a consistent and rigorous review process.
20 Information derived as a product of the research and monitoring of the MRRP will be
21 subjected to the review processes outlined throughout this AMP. Review is also needed
22 for the occasional “new information” that originates outside the Program. That review
23 process will help ensure that the MRRP is using the best available and verifiable science
24 information in informing AM decisions. Under the current structure, this process will
25 progress through the Technical Team and will end up as a topic of review by the
26 Independent Science Advisory Panel, as described in detail in section 2.5.4. The new
27 information process has been used in 2016 for the issue of fish condition, as described in
28 section 4.1.2.4.

29 **6.3 Data and Information Management**

30 **6.3.1 Overview**

31 Adaptive management programs need to manage data in ways that accurately transform
32 information into decision-relevant learning, facilitate and enhance communication,
33 share and protect data appropriately, have a reasonable cost of development and
34 upkeep, and can adapt to changing program needs.

1 The data management system for the MRRP must be able to take a variety of data inputs
 2 generated by the MRRP and by outside sources, perform a variety of functions to
 3 transform that data into actionable and accessible information, and communicate that
 4 information in the right form and time to meet the needs of different user groups
 5 (Figure 96).

6

7 **Figure 96. A conceptual model depicting the management of data to inform the MRRP.**

8 **6.3.1.1 Users and their needs for information**

9 As shown on the right side of Figure 96, there are multiple user groups with widely
 10 varying needs for information on the MRRP. The preferred forms of work products to
 11 meet those needs (described in section 6.3.3.1), include:

- 12
- 13 • succinct summaries of decision-relevant results for decision makers and
 managers;
 - 14 • focused summaries for the bird, fish and HC teams;
 - 15 • non-technical summaries for MRRIC and the general public;
 - 16 • more detailed supporting evidence for the technical staff who advise decision
 makers and managers;
 - 17 • raw and refined data extractable by multiple search criteria for the Technical
 Team and researchers.

21
 22 These information needs will vary at different stages of the AM cycle (as described in
 23 section 6.1), and at different times of the annual cycle (described in section 2.4.2). The

1 following short sections provide an overview of the user groups shown in Figure 96 and
2 their general information needs. These user needs will be defined in much more detail
3 through a User Needs Assessment, to be conducted in the fall of 2016 (described in
4 section 6.3.4.1).

5

6 *6.3.1.1.1 Monitoring staff*

7 The monitoring staff will need to input, QA, and access information generated from the
8 monitoring program, including data, metadata, and derived applications of the data
9 (e.g., population estimates of piping plovers derived from field sampling efforts). The
10 DMS should streamline these processes to enable timely data use and reduce the
11 potential for human error.

12 *6.3.1.1.2 Researchers*

13 Researchers will need to submit data and metadata, as well as research findings and
14 publications. MRRP-funded researchers will have certain rights and obligations
15 regarding data ownership, sharing, and publication as specified in their contracts.
16 Researchers not funded by the MRRP may also submit data, but with different rights
17 and obligations according to their funding sources. Researchers from federal agencies
18 also have obligations for public access to their data. The DMS should facilitate data
19 sharing and permissions to enable researchers to submit and share data as appropriate
20 with minimal time demands, but at the same time assuring that all submitted data is
21 quality assured.

22 *6.3.1.1.3 Technical Team*

23 The Technical Team needs to access a wide variety of information and to ensure the
24 accuracy and completeness of information used in data synthesis and evaluation.
25 Testing hypotheses requires integration of data from diverse sources, and evaluation of
26 many different lines of evidence. Effectively meeting the needs of monitoring staff and
27 researchers will partially fulfill the needs of the Technical Team, as will forms of data
28 organization and evaluation driven by the scientific and learning needs of the AM
29 program. The Technical Team can also benefit from data-processing and reporting tools
30 that automate routine analyses and visualizations to shift time away from repetitive
31 tasks and facilitate prompt reporting.

32 *6.3.1.1.4 Bird, Fish and HC Teams*

33 At the implementation level, staff are both generators and users of monitoring and
34 research information. They require access to on-the-ground decision-relevant

1 information including site-specific monitoring and research results and real-time status
2 of hydrology, species, and habitat. They also require the ability to efficiently quantify
3 and document actions implemented and their outcomes. MRRIC members on the Bird,
4 Fish and HC Teams will have access to data summaries and post-QA/QC data that is not
5 otherwise restricted from release by policy.

6 *6.3.1.1.5 Management and Oversight*

7 Decision makers at the management and oversight levels require ready access to
8 summary and status information, particularly as related to species' objectives and
9 targets, implementation commitments and forthcoming decisions on program actions
10 and expenditures. While most decisions will be guided by information synthesized by
11 the Technical, Bird, Fish and HC Teams, managers and members of the oversight level
12 will also have an interest in directly accessing information; their information needs will
13 be identified, and will likely evolve over time.

14 *6.3.1.1.6 MRRIC and public*

15 Stakeholders, partner agencies, and members of the public have a broad range of
16 information needs and interests, from real-time hydrological data to species status to
17 research findings. In most cases, summaries and information in report-card format will
18 be more useful than raw data sets; in other cases access to more detailed information for
19 those who are interested can be made available after accounting for data sensitivities.
20 Needs, tools, and access requirements for these groups will be determined.

21 **6.3.2 Purpose and Objectives**

22 *6.3.2.1 Objectives of the Data Management System (DMS)*

23 The overall objectives of the MRRP DMS are to:

- 24 1 Provide a portal to information on the MRRP that is specifically designed to
25 meet the needs of researchers, planners, decision makers, stakeholders, and the
26 general public;
- 27 2 Address the needs of a diverse group of data providers and consumers to
28 facilitate efficient planning and execution of the MRRP AM project;
- 29 3 Provide access to the data required for planning and decision making in a timely
30 manner; and
- 31 4 Facilitate awareness amongst related programs in the Missouri River Basin
32 including those not directly part of the MRRP which overlapping interests and
33 information.

1 6.3.2.2 *Principles and Guidelines*

2 The design and development of the DMS will be guided by the following principles:

- 3 1 There will be a commitment to a high level of transparency, recognizing that
4 there may be certain data sets that have access controls associated with them
5 through Federal or other policies.
- 6 2 The system will be designed to minimize the unnecessary duplication of data.
7 The proposed ‘system of systems’ vision is of a dedicated portal to information
8 that is stored on other systems.
- 9 3 Implementation will make use of existing technologies and systems where
10 possible and appropriate. Building on existing systems avoids unnecessarily re-
11 creating what has already been done well.
- 12 4 The identification and reduction of institutional and technological barriers to the
13 sharing of information will be a priority for system design and implementation.
- 14 5 Policies and procedures associated with the DMS will avoid being overly
15 prescriptive about how scientists manage their data while recognizing the need
16 for applying and managing appropriate data quality standards.
- 17 6 The DMS will promote the use of standards for data exchange and reporting.
18 Where data is gathered using program funding, requirements for data provision
19 and reporting will be made explicit.

20 6.3.2.3 *High Level System Requirements*

21 In order for the DMS to be most effective it is critical to understand what information is
22 needed by whom and when and ensure that this information can be provided in
23 required formats with appropriate levels of QC.

24 We are not starting this process from scratch. High-level data management and
25 technology needs and concerns have already been identified within the MRRP and
26 during the EA and AM development processes. At the very highest level the requirement
27 for the DMS can be summarized as:

28 To provide a single user friendly access point for accessing all relevant
29 information on the MRRP so that information required for planning and decision
30 making is available on a timely basis in appropriate formats meeting required
31 quality standards.

1 While the detailed requirements analysis has not yet been completed, some of the
2 candidate high level requirements for the data management system have been identified
3 and are summarized in the following sections.

4 *6.3.2.3.1 Information Stewardship*

- 5 1 Accommodate varied sources and types of information, including information
6 generated external to the program.
- 7 2 Capture and maintain decision-relevant information including monitoring data,
8 research data and findings, supporting information, scientific reports, project
9 performance reports, summary status reports for systems/species, project
10 activity reports, analyses of results of activities, and key reports for decision
11 makers.
- 12 3 Protect MRRP information assets at a level necessary to achieve the desired
13 degree of ownership and user access control, honoring formal data use
14 agreements, legal standards, publication rights, and user rights and
15 responsibilities that are enacted by data owners or delegated custodians.
- 16 4 Capture and document the information used to make decisions.
- 17 5 Accommodate access to legacy data to capitalize on existing MRRP investments
18 when feasible.

19 *6.3.2.3.2 Access to Information*

- 20 6 Provide reliable and timely data access for technical teams and external
21 researchers, facilitating communication and communication of information.
- 22 7 Provide easily searchable meta-data (i.e., data describing the nature of a given
23 data document).
- 24 8 Facilitate and enhance the communication of decision-relevant information
25 through accessible and searchable online interfaces and data visualization tools
26 that are customized to target user groups.
- 27 9 Clarify which data exist, how they have been analyzed and applied, and what
28 further applications they have.
- 29 10 Provide access to near-real-time hydrological data and accompanying
30 visualization tools to help understand the effects of reservoir management on
31 habitat, species, and human considerations.

1 6.3.2.3.3 *Processing and Analysis*

- 2 11 Accelerate learning by processing information into formats that are ready for use
3 by technical staff, managers, partner organizations and stakeholders.
- 4 12 Provide fast, accurate processing of species and habitat information so that
5 outcomes of the previous year's monitoring can be used in the upcoming AM
6 evaluation and decision cycle.
- 7 13 Provide summaries for management, partners and the public.
- 8 14 Ensure tools are practical for use by data generators, saving time rather than
9 creating additional workload.

10 6.3.2.3.4 *System Management and Quality Assurance*

- 11 15 Adjust to changes over time in data, software, and user needs.
- 12 16 Ensure a reasonable cost of development, use, and upkeep.
- 13 17 Establish governed QA/QC standards, tools and processes to ensure information
14 is available and reported promptly.
- 15 18 Facilitate report creation, reducing or eliminating bottlenecks that delay the
16 communication of information, and freeing up staff time spent on conducting
17 repetitive tasks to being able to engage in research.
- 18 19 Maximize accuracy in data acquisition, processing, and reporting by reducing
19 data disparity and providing automated measures of quality.
- 20 20 Maintain data integrity and its measure of uncertainty.

21

22 **6.3.3 Reporting and communication**

23 Data reporting and communication will serve several needs including providing
24 information useful for decision-making as well as fostering understanding of
25 stakeholders and the general public. Each audience has somewhat different needs, and
26 therefore requires different forms of information, with varying levels of detail. These
27 varying needs will be further understood and documented through the user needs
28 assessment in the fall of 2016 (described below in section 6.3.4.1). It will be important to
29 develop, implement, and periodically re-evaluate a communication plan which
30 considers all of the different audiences, and the diverse forms of reporting that are most
31 appropriate to each audience (e.g., decision-oriented syntheses, annual reports,
32 reporting sessions, science workshops, peer-reviewed reports and journal articles, fact

- 1 sheets, videos, presentation summaries). The MRRP generates a wide range of
2 communication products, including all of the above.
- 3 6.3.3.1 *Types of work products*
- 4 Reporting will include annual reporting of system state such as ESH availability,
5 implementation results (what actions were actually undertaken and to what extent),
6 bird and fish monitoring results, progress toward answering big questions and working
7 hypotheses, effects on HCs, and syntheses of the effectiveness of actions.
- 8 Annual and periodic AM reports serve the critical purpose of evaluating effectiveness of
9 management actions toward meeting species objectives, including reporting the status
10 and trends of the three species and their habitats. Annual reports have been very
11 successfully used in the Platte River Recovery Implementation Program (PRRIP)¹,
12 particularly as these reports are accompanied by an annual AM Plan Reporting Session
13 in which the previous year's findings are presented and discussed. AM reports also
14 include a MRRP score card that communicates the status of new learning in relation to
15 management hypotheses (see Table 53 in section 4.6 for a possible score card approach
16 for synthesizing multiple lines of evidence related to pallid sturgeon action hypotheses).
- 17 The AM Report contains recommendations from the Bird, Fish and HC Teams for
18 adjustments to management actions and suggestions for prioritizing research,
19 monitoring assessment and other Program activities in development of the annual
20 MRRP Work Plan. The Annual AM Report is the primary vehicle for summarizing
21 research, monitoring and data analysis results in a manner that ensures new learning is
22 incorporated into MRRP decisions and that these decisions are made based upon the
23 best available science. AM reports will be made available to the Management Team,
24 agency leadership, MRRIC and the ISAP for their review and recommendations.
25 Effecting sharing and maximum transparency of the information used in decision-
26 making will be a key guiding principal in reporting.
- 27 To translate scientific information and communicate results and recommendations, a
28 series of work products will be produced. Table 56 outlines the products and identifies
29 various user groups listed as both preparing and receiving work products. Since each
30 user group has a diverse composition and occasional turnover, and a need for
31 documenting past results exists, requiring information transfer both within and between

¹ The PRRIP "State of the Platte Report" (e.g., PRRIP 2014) has proved to be a very effective communication tool. The report is organized hierarchically, providing a tabular summary of current understanding of the answers to 11 Big Questions (for decision makers), 3 to 5 page syntheses of evidence for each Big Question and related hypotheses, specific subsections on 'decision implications', recommendations from the PRRIP Independent Science Advisory Committee (ISAC) and responses to these recommendations, and hyper-linked endnotes to all of the primary reports and references used as evidence.

1 groups. There are also diverse levels of interest in technical information within MRRIC
 2 and the general public; providing a hierarchy of linked information (from high-level
 3 report cards down to detailed technical reports from which summary information is
 4 derived) will permit different users to dive into the details as deep as they'd like.
 5

6 **Table 56. Work product and other forms of information access.**

Work Product / Information Access	Purpose/Message	Prepared By	Primary Audience
Online Portal to Raw Monitoring Data (see section 6.3.6)	Access raw data and metadata for scientific analyses (e.g., test hypotheses, improve models, assess status and trends) Allow upload of quality-assured data Restrict access to some data	Data providers Research scientists Technical Team Information Management Team	Research scientists Technical Team
Online Portal to Data Summaries and all Work Products	Status and trends of projects, habitats, species, and HC indicators at various spatial scales Quickly generate maps, graphs and tables for other work products Apply exploratory tools (e.g., Hydroviz) Provide single entry point to other work products	Research scientists Technical Team Information Management Team	Technical Team Management Team Scientific community Bird, Fish and HC Teams Independent Panel MRRIC General Public
Technical Reports	Analysis of monitoring data Modification of conceptual ecological models Evaluation of hypotheses and big questions related to tern, plover and pallid sturgeon population dynamics Reports on effects of actions on HCs	Technical Team	Technical Team Management Team Scientific community, Bird, Fish and HC Teams, Independent Panel MRRIC
Fall Science Meeting	Review initial observations from the field season regarding the system Describe project performance and monitoring Identify analytical needs Serve as an in-Progress Review (IPR) Allow Water Management to provide a briefing on the draft AOP	Management Team Technical Team Research scientists	Oversight Team Management Team Technical Team Bird, Fish and HC Teams Independent Panel MRRIC

1

2 **6.3.3.2 Product approvals**

3 The USACE has final approval responsibility for products and deliverables that are the
 4 responsibility of the MRRP. This approval process follows the steps as outlined by The
 5 USACE and the Division Commander has the final authority on any product approval.
 6 However, because of the collaborative nature of the Program and the need to delegate
 7 approval for some products to a more appropriate organizational level, the approving
 8 entity varies with the specific product and, in some cases, involves signatures from
 9 cooperating agencies.

10 **6.3.3.3 Timing and distribution mechanism for products**

11 The timing of delivery of information (and various work products) will be driven by
 12 three processes: 1) the need for very rapid information to manage water during each
 13 year; 2) the ongoing process of learning by the Technical Team and research scientists,
 14 which requires rapid access to multiple forms of quality-assured information; and 3) the
 15 annual cycle of AM governance (described in section 2.4.2).

16 **6.3.4 Proposed work plan for developing the Data Management System (DMS)**

17 The proposed work plan for the development of the DMS consists of a series of phases,
 18 starting with a careful analysis of the users and their diverse requirements, followed by a
 19 review of these requirements involving MRRP stakeholders to ensure accuracy and
 20 completeness.

1 After the requirements analysis and documentation, the development process will
2 proceed through system design and implementation phases. In this section we focus on
3 the requirements analysis. The later phases will be documented in more detail once the
4 requirements have been clearly defined.

5 *6.3.4.1 Requirements Analysis*

6 The requirements analysis includes a research component followed by documentation
7 and review.

8 *6.3.4.1.1 Objectives of Requirements Research*

9 The overall objective of the requirements research will be to describe the functions and
10 work products each user group will require, what specific products should be available
11 to them on what time schedule, and how they will interact with the DMS. More
12 specifically:

- 13 1. What information should be available, to whom, when, through what
14 interface/process, in what format, and with what quality standards?
- 15 2. How should the different data sets and information products be stored and
16 accessed?
- 17 3. What metadata needs to be maintained to ensure data is properly described and
18 is accessible in the simplest way possible given any access controls?
- 19 4. What processes and procedures need to be in place for data management at all
20 levels, for example QC?
- 21 5. What are the business processes and timelines that should drive the data
22 management process?

23 These questions will be addressed through consultations with potential DMS users
24 including both data providers and consumers, background research on the capabilities
25 of existing systems, and identification of the key barriers to meeting system objectives.

26 *6.3.4.1.2 Task 1: User Needs Assessment*

27 A list of information and data needs will be compiled from the AMP, organized into
28 meaningful categories, and used as a starting point for eliciting feedback and input from
29 a wide range of different potential users of the DMS. This compilation will be designed
30 to allow potential users to focus on their specific areas of interest based on their roles
31 with the MRRP.

1 The compilation will be developed in collaboration with the core team and then shared
2 more broadly with people across a range of expected DMS users. A more complete
3 articulation of user needs will be built through a mix of individual review and feedback
4 as well as small group discussions. It will be important to many different aspects of the
5 user community involved, and to make wise use of existing committees, subgroups, and
6 protocols for interaction.

7

8 *6.3.4.1.3 Task 2: Review of Existing Systems*

9 Existing systems will be reviewed from several different perspectives:

- 10 • Existing data and information sources currently relevant to the MRRP that will
11 need to be incorporated into the overall system of systems – see section 6.3.6
12 below;
- 13 • Portal systems that can be used to provide examples of different functionality and
14 user interface approaches – see section 6.3.5.3; and
- 15 • Systems that could potentially be used as part of the technology for developing
16 the DMS.

17 Candidate systems for review will be elicited both from the core team and other users
18 during Task 1.

19 *6.3.4.1.4 Task 3: Identification of Barriers to Implementation*

20 Barriers to implementation will be researched in a number of ways, including during the
21 identification of user needs in Task 1. It will be important to understand what current
22 limitations and issues are faced by MRRP data and information users so that we can
23 ensure that these are addressed as far as possible in the DMS. Some of the issues to be
24 considered include:

- 25 • Data funded in one program may be hard to share with another;
- 26 • Researchers unwilling to share data before publishing;
- 27 • Institutional and policy barriers to sharing specific types of data; and
- 28 • Format and data documentation issues.

29 The MRRP will not be the first data management initiative to encounter these types of
30 issues and it will be important to learn from others. The Long Term Ecological Research
31 Network (<https://lternet.edu/>) has done considerable work resolving these types of
32 issues and will be a valuable source of information.

1 6.3.4.1.5 *Task 4: Requirements Review and Final Requirements Documentation*

2 The results of the user needs assessment in Task 1 and the research into existing systems
3 and barriers to implementation in Tasks 2 and 3 will be compiled into a set of draft
4 requirements for review. The review process has not yet been finalized but will involve
5 an initial review by the core team followed by a wider review by a larger group of MRRP
6 stakeholders who are interested in the DMS.

7 6.3.4.1.6 *Schedule*

8 The proposed schedule for completing the requirements analysis is:

9 Task 1. User needs assessment – September 2016 to January 2017

10 Task 2. Review of existing systems – October 2016 to January 2017

11 Task 3. Identification of barriers – October 2016 to January 2017

12 Task 4. Requirements review and final documentation – February to April 2017

13 It is proposed that the detailed design of the DMS will continue through 2017 with
14 implementation starting in 2018 following approval of the AM Plan.

15 6.3.4.2 *User Needs Assessment*

16 The user needs assessment will begin in the latter part of 2016. In this section we
17 describe some of the considerations to be included in the assessment.

18 6.3.4.2.1 *Participation*

19 The user needs assessment will be structured around broad types of users in order to
20 focus on issues most relevant to these roles. The proposed user groups directly related
21 to the MRRP have been described in section 6.3.1.1 and include:

- 22 • Monitoring staff,
23 • Researchers working on the Missouri River and its major tributaries,
24 • Technical Team,
25 • Bird, Fish and HC Teams,
26 • Management Team
27 • Oversight Team,
28 • MRRIC members, and
29 • Interested general public.

30 Participants may also be broadened to include researchers and groups involved in other
31 programs with similar interests to the MRRP.

1 Specific groups and individuals within those groups will be identified for participation in
2 this task based on discussion with the MRRP core team.

3 *6.3.4.2.2 Topics to be Covered*

4 The structure for determining user needs will be further developed as Task 1 process.
5 Here we present some initial topics that will be covered based on our preliminary
6 discussions and analysis.

7 Topics for all participants:

- 8 1. Tools/systems/or data sources that are important for us to consider as we
9 develop the DMS

10 Topics to cover in the user needs assessment for information providers:

- 11 2. Types of information currently generated that is relevant to the MRRP, e.g.
12 • Monitoring data
13 • Research reports
14 • Summary reports
15 • Data portals available to a wider audience
16 • GIS data available to a wider audience
17 3. Additional types of information that could be provided
18 4. Current access controls or restrictions on data access and sharing of this
19 information, e.g.
20 • Information is public
21 • Data access agreements required for sharing.
22 • Information has strong privacy/confidentiality restrictions.
23 • Specific controls you would like to see on your data...?

24 Topics to cover in the user needs assessment for information consumers:

- 25 5. Information critical to each role related to MRRP
26 6. Information needed for one or more roles that is not currently available
27 7. Technical or institutional barriers currently hampering access to information
28 8. Ideas on how to address these hurdles
29 9. Requirements for this information in specific formats or with particular
30 summaries
31 10. Preferred format and access methods
32 11. Specific milestones/decision points when this information is needed (on an
33 annual cycle)

- 1 12. Currently methods of accessing information on the MRRP
- 2 13. Data quality standards required for the information used by different user groups

3 *6.3.4.3 DMS Development and Implementation*

4 Following the completion of the requirements process the DMS will move into the
5 implementation phase. At this point there has been no decision on the details of the
6 implementation approach and this will likely depend on the selection of the agency
7 and/or team who will lead the development. We would expect that there will be a system
8 design phase where there would be input from appropriate members of the MRRP team,
9 as well as information technology experts within the USACE.

10 Some of the decisions to be made early on in this phase will be around:

- 11 • priorities for development;
- 12 • the use of existing platforms and tools;
- 13 • the selection of the development team; and
- 14 • hosting options.

15 In addition to the requirements for DMS functionality these decisions will also need to
16 take into account budgetary and scheduling constraints, and the approach to be taken to
17 the long term management, operation, and maintenance of the DMS.

18 A key task in developing the implementation approach will be developing a plan for
19 phasing and scheduling. The schedule will depend on the complexity of the overall
20 design, the priority for different requirements, and budgetary constraints.

21 Several technology solutions supporting MRRP monitoring programs are already in
22 place). Fusing newly-developed technology with existing MRRP investments where
23 feasible will provide a foundation for decision support that can grow as priorities shift
24 with the AM process. Suitable technology development to support the dynamic MRRP
25 will be able to evolve over time without having to be rebuilt from scratch when
26 programmatic needs shift. The technology architecture and components will be built to
27 come and go while the rest of the system remains completely operable.

28 **6.3.5 DMS Structure and Functionality**

29 The products needed to address MRRP needs will include websites, analytic software,
30 dashboards, databases, catalogues, maps, and reports. All technology products share a
31 need for some common functionality, such as a secure computing environment,
32 information (metadata) about where the data came from, and its attributes (e.g.,

1 locations and times sampled, sampling design, monitoring protocols, methods of
2 computing metrics, precision, accuracy). To make development effective and efficient,
3 the same structure will be used for all common functionality when possible across all
4 MRRP systems.

5 *6.3.5.1 User Interface Components*

6 While the details of the data management system design will be developed during the
7 requirements analysis, experience with other similar systems provides a basis for
8 considering some of the different functionality that may be included.

9 1. General Information and Communication

- 10 • Calendars of events related to MRRP
11 • News feeds/significant events related to project components, timelines,
12 results etc.

13 2. Compiled and Summarized Information interfaces

- 14 • Dashboards showing the system status (projects, habitat, species'
15 abundance, flows, reservoir levels, river stage)
16 • Report cards focused on key issues (e.g., state of current understanding
17 with respect to key hypotheses)

18 3. Data access

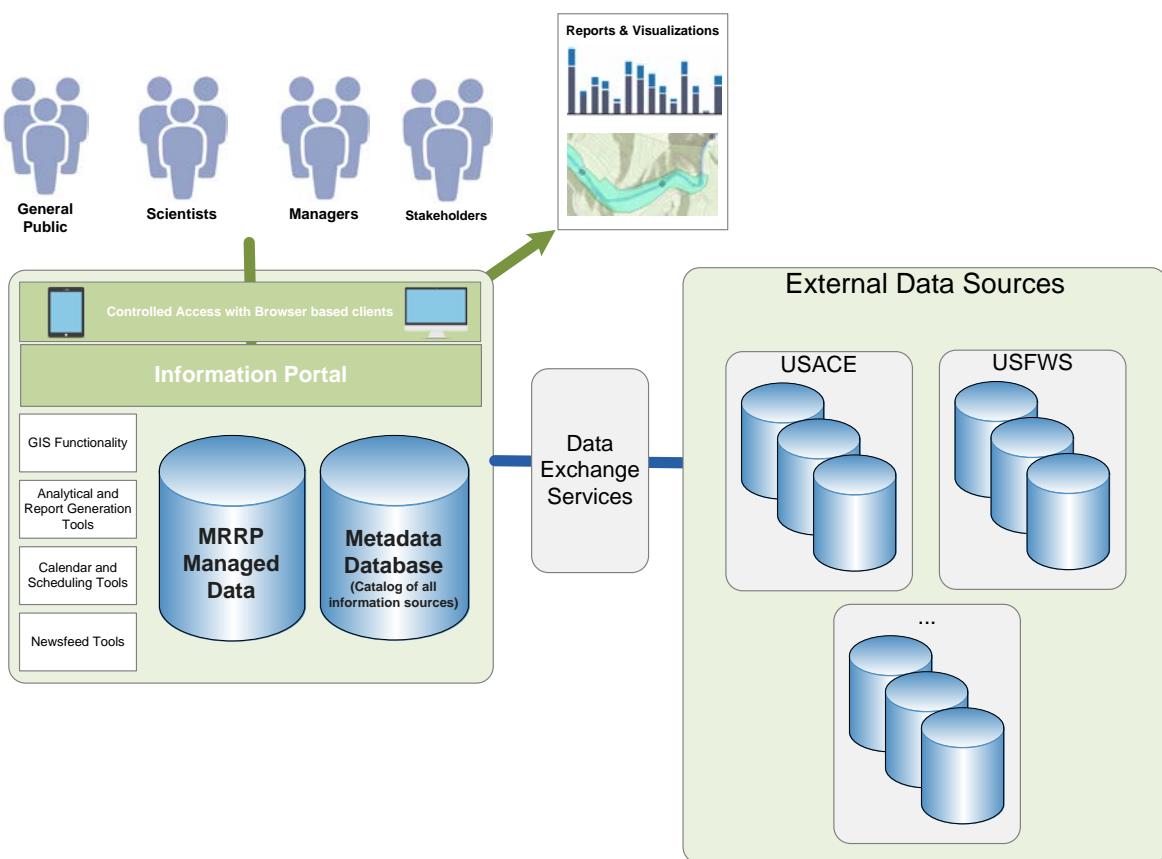

- 19 • Tabular/text based interfaces for finding and viewing information using
20 searchable metadata
21 • GIS/Mapping interfaces for finding and viewing information

22 4. Analytical tools

- 23 • Automated report generation and/or query engine to produce charts and
24 tabular results tables, for example for hydrological data
25 • Access to analytical software operating on raw data such as demographic
26 models for birds and fish, habitat models, floodplain models.

27 *6.3.5.2 Conceptual Architecture*

28 Based on the principles, guidelines, and high level objectives described in the previous
29 sections we can describe a conceptual architecture for the DMS as shown in Figure 97.

1

2

Figure 97. Conceptual Architecture for the MRRP DMS

3 The key components to note in this architecture are:

- 4 1. A single portal to all required information and tools for all user types;
- 5 2. Controlled access for certain information and tools based on the requirements of
- 6 the data and tool providers;
- 7 3. The majority of data maintained in systems controlled by the agencies currently
- 8 generating and managing that data (right side of Figure 97) with a smaller
- 9 amount of MRRP specific data managed directly by the DMS (left side of Figure
- 10 97);
- 11 4. Data exchange services based on defined standards to allow direct access to data
- 12 from the DMS across multiple systems;
- 13 5. A comprehensive and searchable metadata database describing data sources and
- 14 information in all locations; and
- 15 6. A variety of user friendly tools to facilitate finding and accessing information in
- 16 user friendly tabular and map based formats.

1 6.3.5.3 *Information management portal examples*

2 The MRRP Data Management System will not be the first system to address many of the
3 requirements that have been identified. While it is too early to in the design and
4 development process to focus on the details of user interface design it can still be useful
5 to consider other systems and how effective they have been in addressing these
6 requirements. Reviewing these related systems also provides a more concrete basis for
7 discussion of user needs and options during the requirements analysis phase.

8 6.3.5.3.1 *The Long Term Ecological Research Network (LTER)*

9 The LTER Network site (<https://lternet.edu/>) demonstrates some of the characteristics
10 and functionality being considered for the MRRP DMS:

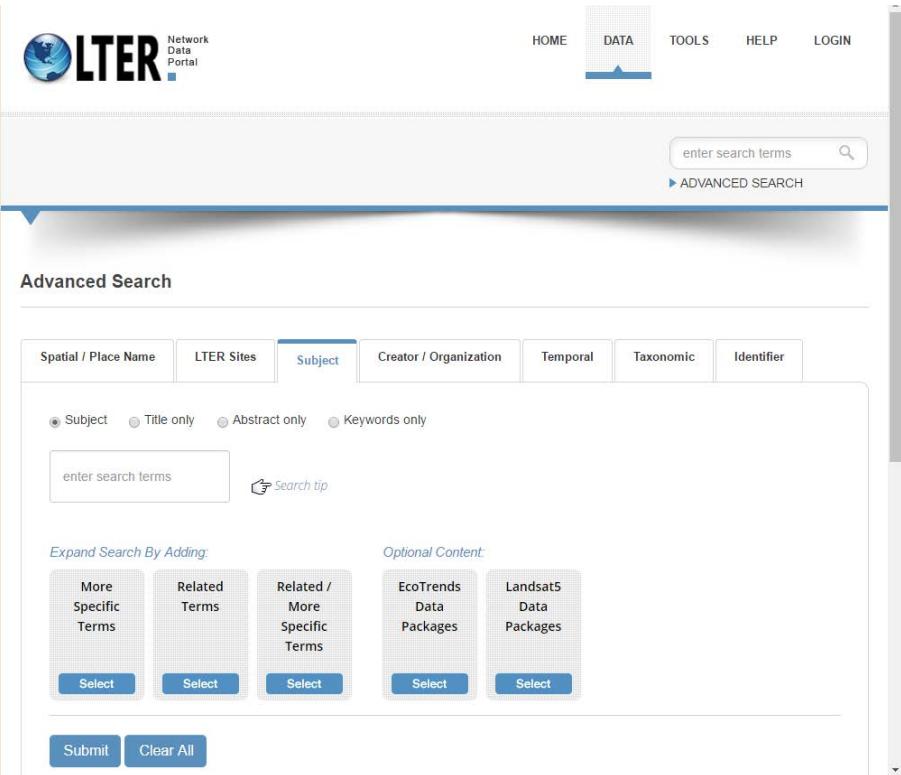

- 11 • Clean user interface with role rapid entry points on the top of the first page: “For
12 Researchers”, “For Educators & Students”, “For Decision Makers”;
- 13 • Access to a data portal;
- 14 • A news feed;
- 15 • Featured information/sites of current interest; and
- 16 • Some background information on the network.

17

18 19 Figure 98. Portal example from LTER Network

- 1 Links from the main page connect to a range of tools and background information
 2 including sections on requirements for data management plans.
 3 The data portal for the LTER Network (<https://portal.lternet.edu/nis/home.jsp>) allows
 4 browsing and searching through data packages. A Map Portal
 5 (<https://lternet.edu/sites/map>) provides a simple map-based interface for accessing
 6 information on different sites and projects.

7

The screenshot shows the 'Advanced Search' page of the LTER Network. At the top, there is a header with the LTER logo, 'Network Data Portal', and navigation links for HOME, DATA, TOOLS, HELP, and LOGIN. Below the header is a search bar with a placeholder 'enter search terms' and a magnifying glass icon. To the right of the search bar is a link to 'ADVANCED SEARCH'. The main search area is titled 'Advanced Search' and includes several search categories: 'Spatial / Place Name', 'LTER Sites', 'Subject' (which is selected), 'Creator / Organization', 'Temporal', 'Taxonomic', and 'Identifier'. Below these categories are four radio buttons: 'Subject' (selected), 'Title only', 'Abstract only', and 'Keywords only'. There is also a 'Search tip' link next to a search input field. Further down, there are sections for 'Expand Search By Adding:' and 'Optional Content:'. Under 'Expand Search By Adding:', there are four buttons: 'More Specific Terms', 'Related Terms', 'Related / More Specific Terms', and 'EcoTrends Data Packages'. Each button has a 'Select' button below it. Under 'Optional Content:', there are two buttons: 'Landsat5 Data Packages' and another 'Select' button. At the bottom of the search form are 'Submit' and 'Clear All' buttons.

8

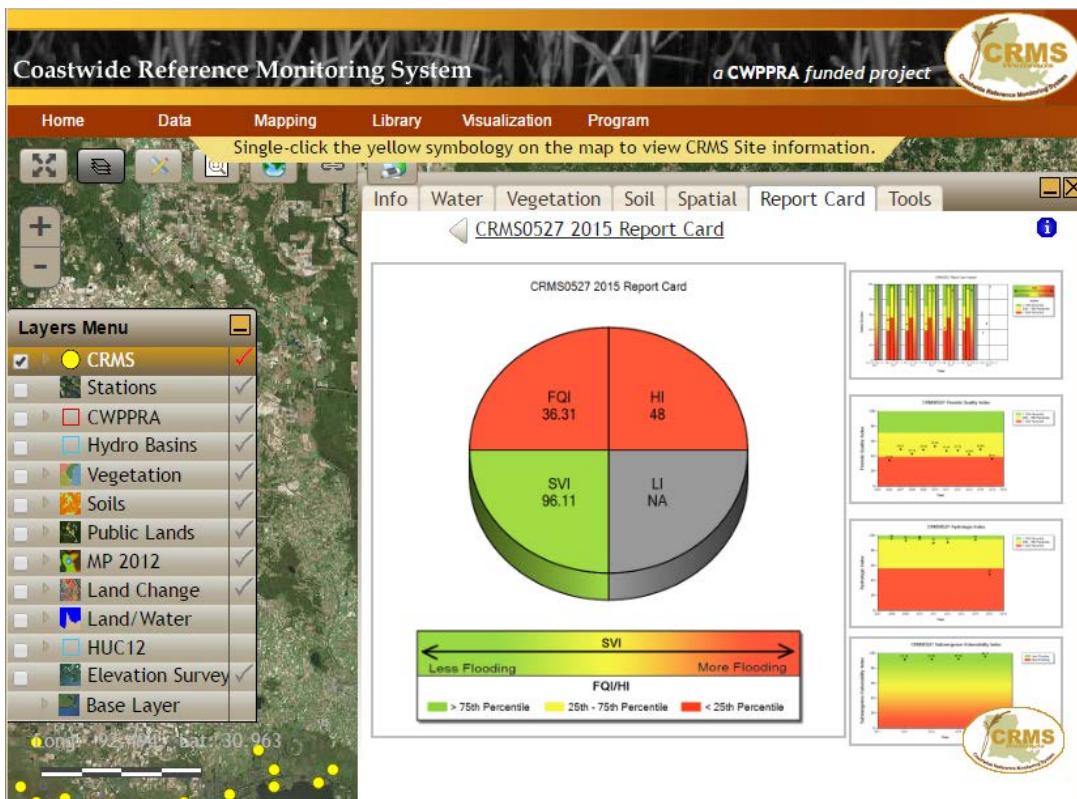

9 Figure 99. Advanced metadata catalog search example from LTER Network

10 6.3.5.3.2 *Louisiana Coastal Wetlands Planning, Protection and Restoration*
 11 (*CWPPRA*)

- 12 The CWPPRA site (<http://lacoast.gov/new/Default.aspx>) and associated Coastwide
 13 Reference Monitoring System provide (CRMS) (<http://lacoast.gov/crms2/home.aspx>)
 14 provide another example of some of the functionality being considered. As for the LTER
 15 Network site there is a main landing page with background information, current
 16 events/news, and linkages to a range of tools and background information.
 17
 18 The CRMS interface is focused more specifically on access to information through a
 19 range of different tools.

1 The system includes a full GIS interface with automated generation of report cards and
2 other data summaries.

3

4 Figure 100. GIS interface with Report Cards example from the CRMS Portal
5

6 7 6.3.5.3.3 Colorado State University – eRAMS

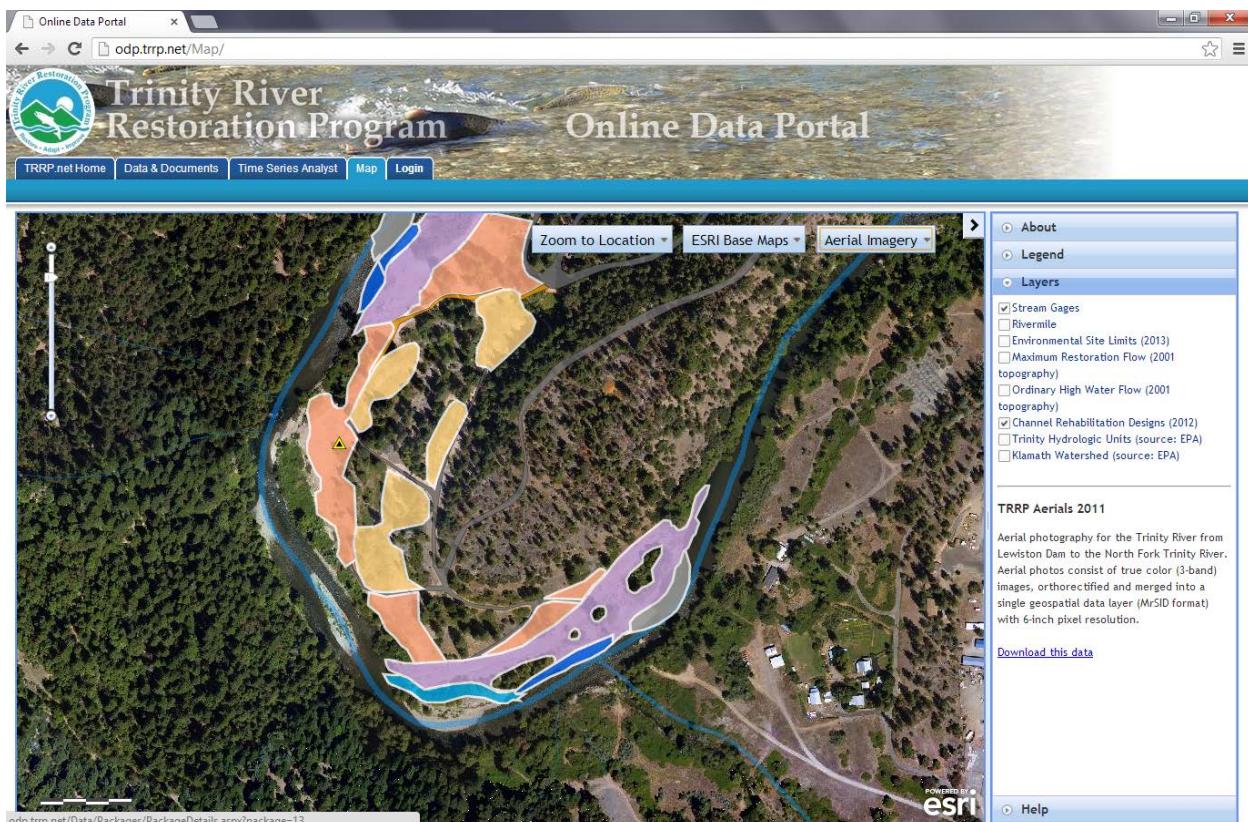

8 The eRAMS (<https://erams.com/>) system is a platform for building accessible and
9 scalable analytical tools and models. As such it can both provide examples of ways of
10 addressing MRRP requirements but could also be considered as a platform for
11 implementing the MRRP DMS. The eRAMS system utilizes the Amazon cloud and has
12 access to a wide range of publically available data including USGS Stage data.

13 Of particular note for the eRAMS system is its ability to support models based on both
14 publically accessible and other data such as the flow analysis toolkit. A large array of
15 these tools have already been developed and are available; other enterprise tools could
16 be developed to meet specific needs of the MRRP community.

1 6.3.5.3.4 *Trinity River Restoration Program Online Data Portal (TRRP.net)*

2 The Trinity ODP (<http://odp.trrp.net>) addresses many of the same requirements as the
3 MRRP DMS; searchable metadata for a wide range of different reports and data sources,
4 a map based interface, and customized tools for time series analysis of specific data sets.
5 The ODP software is in the public domain and structured to be easily transferred to
6 other river basins. A video demonstration is available at:
7 <https://www.youtube.com/watch?v=GtyG3mb09TI>

8

9 10 Figure 101. GIS interface example from the Trinity Online Data Portal

11 6.3.6 **Integrating Existing Data Management Systems**

12 The decision to integrate, migrate, or adapt existing technologies will be based on the
13 needs and priorities of the AM objectives being evaluated. In some cases, it may be
14 sufficient to leverage existing data management assets, particularly if users find that
15 they are working well. In other cases, an adapted or new solution may be required. A
16 phased approach may also be used to gradually shift functionality to newer systems, by
17 first adapting existing systems, if source code is available. For legacy commercial
18 products that cannot be modified, migration may be the best option.

1 Several existing monitoring program data management systems are catalogued below,
2 which were previously developed to provide centralized collection, storage, and
3 dissemination of piping plover and least tern survey data, and pallid sturgeon survey
4 data from the Missouri River Basin. Collectively, these systems also support
5 maintenance of data quality standards for survey data and provision of real time
6 information for decision-making processes.

7 *6.3.6.1 Least Tern and Piping Plover Data Management System (TPDMS)*

8 <https://rsgisias.crrel.usace.army.mil/intro/dms.dmsintro.main>

9 The Tern and Plover Data Management System (TPDMS) was designed to enter, store,
10 maintain, and disseminate data from the Tern and Plover monitoring program. During
11 the field season data are updated on a daily basis by field crews, using ESRI's ArcPad
12 software on Trimble GPS units. Field software provides immediate QA/QC of data
13 entries in the field. Data entry has been streamlined using an upload process on the
14 website which loads data files from the GPS units directly into the Oracle database. The
15 TPDMS web interface provides a portal to real time and historic reports, a map
16 interface, data entry modules, and tools for field crews. Built in validation routines and
17 manual approval provide for rigorous data standards and ensure quality data are
18 available for reports and data presentation which can be used by partners and decision
19 makers. The system provides multiple levels of access to the data and information
20 ensuring data integrity. A username and password are required to gain access to the
21 system due to the sensitivity of data on the location of endangered species. Access can be
22 requested online through the website.

23 *6.3.6.2 Pallid Sturgeon Population Assessment Website (PSPA Website)*

24 The Pallid Sturgeon Population Assessment Website was designed as a tool for field
25 crews to enter and maintain data for the Pallid Sturgeon Population Assessment
26 Program (PSPAP) and Habitat and Mapping Program (HAMP). Field data are collected
27 electronically using a custom-built MS Access application on Xplore tablets with
28 integrated GPS capability. The field application contains built-in validation routines
29 providing for QA/QC in the field while the data are being collected. The website
30 provides a portal where files from field computers can be directly uploaded into the
31 Oracle database making it available to users immediately. Tools for field crews and
32 additional validation routines have been built into the PSPA website to further improve
33 data quality. This system is currently only available to field offices collecting the data
34 and to the data administrators. Public content has yet to be developed.

1 Appendix D to this Plan proposes a substantial revision to the current protocols for
2 population monitoring, which will be reflected in the software used for data collection.

3 Current protocols for requesting data from the PSPAP require a data request for each
4 analysis which must be approved by the PSPAP teams. This step will typically be
5 unnecessary in the future because key analyses and certified information users will be
6 identified ahead of time. Only unplanned analyses from new information users will
7 require additional coordination and approvals from monitoring teams, likely following
8 protocols similar to those currently existing in the PSPAP.

9 *6.3.6.3 Pallid Sturgeon Collaborative Population Dynamics Model*

10 This model is described in Jacobson et al. (2016a) and summarized in section 4.1.2.3
11 and Appendix D of this AM Plan. The EA team has developed and deployed a version of
12 the model online as a proof of concept (see
13 https://mcolvin.shinyapps.io/pallid_sturgeon/). A basic version of the model will be
14 deployed on the web, permitting users to explore the outcomes of different actions and
15 hypotheses over 50-year time periods, and incorporating random variation to reflect
16 uncertainty in both environmental conditions and functional relationships. The
17 Technical Team will use a combination of the web based tool and a local application
18 which permits greater complexity in various attributes (e.g., spatial resolution,
19 stochastic replication, individual based models, time horizon), although if the online
20 model is hosted on an internal server, then various constraints may be reduced.

21 *6.3.6.4 USFWS National Pallid Sturgeon Database (NPSDB)*

22 https://www.fws.gov/moriver/pallid/pallid_search.cfm

23 The purpose of the National Pallid Sturgeon Database is to compile, store, and
24 disseminate all data on pallid sturgeon captures, across the range of the species, to
25 support recovery efforts. The database is also used to record stocking data for the pallid
26 sturgeon propagation program. An online tool has been developed to provide access to
27 simple recapture histories of individual fish based on PIT tag number. More complete
28 datasets are shared with programs such as PSPAP on an annual basis after the data from
29 all programs have been compiled.

30 *6.3.6.5 Pallid Sturgeon Genetics Data*

31 All entities involved in pallid sturgeon monitoring and research are required by the
32 USFWS to collect genetics samples from pallid sturgeon lacking identifiable hatchery
33 marks. Genetics samples are sent to several different labs depending on analysis needs.

1 These data are recorded on a standardized genetics datasheet which is included with
2 each sample and stored and maintained by the respective genetics lab. Information on
3 the capture location, ancillary information, and the genetics sample ID are incorporated
4 into the NPSDB. Genetics information is valuable for many purposes, including relating
5 surviving offspring to their parents.

6 6.3.6.6 *Hydrologic Engineering Center River Analysis System HEC-RAS*

7 <http://www.hec.usace.army.mil/software/hec-ras/>

8 This software allows the user to perform calculations of one-dimensional steady flow, 1
9 and 2-dimensional unsteady flow, sediment transport, mobile bed movement, water
10 temperature and water quality. HEC-RAS is a foundational tool used to support
11 geomorphic calculations for both bird and fish habitat applications, as well as to support
12 estimates of effects on human considerations.

13 6.3.6.7 *Hydrologic Engineering Center Reservoir System Simulation*

14 <http://www.hec.usace.army.mil/software/hec-ressim/>

15 The Reservoir System Simulation (HEC-ResSim) software (developed by the U.S. Army
16 Corps of Engineers, Institute for Water Resources, Hydrologic Engineering Center) is
17 used to model reservoir operations at one or more reservoirs for a variety of operational
18 goals and constraints. The software simulates reservoir operations for flood
19 management, low flow augmentation and water supply for planning studies, detailed
20 reservoir regulation plan investigations, and real-time decision support. HEC-ResSim
21 can represent both large and small scale reservoirs and reservoir systems through a
22 network of elements (junctions, routing reaches, diversion, and reservoirs) that the user
23 builds. The software can simulate single events or a full period-of-record using available
24 time-steps. HEC-ResSim is a decision support tool that meets the needs of modelers
25 performing reservoir project studies as well as meeting the needs of reservoir regulators
26 during real-time events, to minimize impacts on human considerations.

27 6.3.6.8 *Missouri River Basin Water Management Information*

28 The MRBWM office maintains a public website at www.nwd-mr.usace.army.mil/rcc.
29 This site contains information concerning System regulation. The website includes
30 forecasted reservoir levels and dam releases as well as historic data in both tabular and
31 graphic formats. It contains user-friendly, clickable maps to observe graphical
32 streamflow and System project data. The MRBWM office performs streamflow
33 forecasting at select locations and these results are provided for comparison to the

1 official NWS forecast. The NWS forecasts are available as a link from the MRBWM
2 website. The website contains special news releases regarding closure of the river for
3 navigation during extremely large flood events, deviations from proposed regulation
4 plans, water control plan information meetings, nesting operations of threatened and
5 endangered species, and other significant items that occur on an unscheduled basis. In
6 addition, the USACE produces numerous public reports on a daily basis that provide
7 continual updates of the System's status, recent activities and changes in regulation of
8 reservoirs. These reports are available to the public on the MRBWM website or by email.

9 6.3.6.9 *Comprehensive Sturgeon Research Project (CSRP)*

10 CSRP datasets describe the locations, movements, physiological indicators, and genetics
11 of individual monitored fish, as well as ancillary data related to water temperature,
12 water quality, habitat availability, and habitat use. The bulk of the data reside in two
13 datasets housed at the USGS, Columbia Environmental Research Center, Columbia,
14 MO: 1) The Sturgeon Information Management System (SIMS), and 2) the Missouri
15 River Hydroacoustic Habitat Dynamics System (MRHHDS). More information on these
16 databases is available in Jacobson et al. 2015a. Access to these datasets can be arranged
17 through requests to the chief of the River Studies Branch, USGS–CERC, Columbia, Mo.

18 6.3.6.10 *Pallid Sturgeon Research literature database*

19 The Pallid Sturgeon Effects Analysis team has created an Endnote™ database (Thomson
20 Reuters New York, New York) with links to literature cited in the EA reports. This
21 database is meant to be an archival record of information sources and will be sharable
22 among agencies and scientists working on pallid sturgeon recovery, subject to applicable
23 copyright laws. This database contains literature citations for scientific information
24 relevant to understanding pallid sturgeon population dynamics, Missouri River physical
25 and chemical processes, riverine ecology, flood plain ecology, and other native and
26 nonnative species. The Endnote™ database and library assembled for the pallid
27 sturgeon EA is limited to sources cited in the EA documents; however, a larger database
28 and library is maintained by USGS–CERC, which contains records related to river
29 processes, native, and endangered species.

30 6.3.6.11 *Physical Habitat Assessment Data*

31 Physical survey data is available from both the Kansas City and Omaha districts
32 Hydrology and Hydraulic Branches. Data include bathymetry surveys, sediment-sample
33 collection, acoustic Doppler current profiles, and two-dimensional hydrodynamic
34 models. The Kansas City district has developed a software package called Cross Section
35 Viewer which was designed for storage and retrieval of cross section data.

1 6.3.6.12 *Water quality data*

2 Currently water quality data are collected by each district. Specific needs for water
3 quality data have been described in Chapter 4 of this plan, and in Appendix K.

4 6.3.6.13 *USGS National Water Information System*

5 <http://waterdata.usgs.gov/nwis>

6 The USGS National Water Information System provides access to water-resources data
7 collected across the nation, including the Missouri River basin. The USGS investigates
8 the occurrence, quantity, quality, distribution, and movement of surface and
9 underground waters and disseminates the data to the public, State and local
10 governments, public and private utilities, and other Federal agencies involved with
11 managing water resources. Information available through this site include surface
12 water, groundwater, water quality, and water use data.

13 6.3.6.14 *Monitoring of Emergent Sandbar Habitat*

14 Data that accounts for ESH characteristics are collected and available through the
15 MRRP ISP. Datasets include satellite imagery, remote sensing habitat classifications
16 generated from satellite imagery, ESH accounting summary datasets, and habitat
17 quality line intercept data. Imagery data are stored on a local GIS server and also
18 provided to the Omaha district GIS Service Center for storage and dissemination. All
19 other datasets are stored on local servers with the ISP and are available on
20 request.Moriverrecovery.org

21 The [moriverrecovery.org](http://Moriverrecovery.org) website is the public portal to the MRRP. It provides access
22 to current status of the MRRP, the Missouri River basin model, tribal and MRRIC links,
23 MRRP documents library, and background information on all MRRP implementation,
24 planning, monitoring, and research projects. A mapping component provides for spatial
25 exploration of the basin. It is envisioned that this website will provide a mechanism for
26 timely sharing of monitoring and research results to the public.

27 **6.3.7 Responding to existing and emerging information needs**

28 The MRRP has established an Information Management team to provide input to the
29 approach and stewardship of data management and technology planning for the AM
30 process. The Information Management team will support all information users, and
31 determine how to best provide information to support existing and emerging needs in
32 the AM process. Examples of information needs that have already been identified
33 include:

- 1 • a unified catalogue of existing data;
- 2 • improved integration of plover population data with emergent sandbar habitat
- 3 assessments;
- 4 • near real-time planning support for water managers with respect to potential
- 5 plover nest take;
- 6 • improved dissemination and integration of hatchery-to-hatchery and hatchery-
- 7 to-river data to integrate and clearly communicate historical and current fish
- 8 tracking information;
- 9 • provide complete time series of hydrologic and climate variables, for the
- 10 Technical Team and other scientists; and
- 11 • integration of pallid sturgeon data from multiple sources.

12 Once a new information need is identified, the Information Management team will
13 conduct the following steps:

- 14 a. gain a better understanding of existing data and components (databases,
15 websites, spreadsheets, etc.) that may or will exist, determine who the
16 custodian(s) is/are of the data, identify where and how the data are being stored,
17 and how the data may or may not be connected;
- 18 b. identify potential users of the data and how a product that provides a view of the
19 data can be tailored to each specific user group to maximize its value and utility;
- 20 c. identify any sensitivities that may be associated with the data to provide the
21 appropriate level of security;
- 22 d. determine the appropriate time interval by which the data must be updated;
- 23 e. define who will maintain the data , and how;
- 24 f. determine when and how often endpoints (websites, desktop applications, etc.)
25 will be reviewed to determine their continued relevance to the program and
26 identify any necessary modifications;
- 27 g. facilitate access to all relevant data, manage the development of system
28 conceptual models and architecture, define QA/QC standards and deployment
29 considerations;
- 30 h. create or modify systems to address existing and future needs that may be
31 identified (e.g., websites, software, reporting products)
- 32 i. subject all websites, software, reports or other products to an internal review and
33 user group testing before final deployment.

34 **Quality assurance and quality control**

35 A complex process will be required to collect, organize and rapidly assess all of the data
36 required to support the MRRP AM Plan. That complexity in turn requires a systematic

1 process for data QC, to ensure that decision-makers and stakeholders have confidence
2 that the data used to support decisions are scientifically sound, of known and
3 documented quality, and suitable for their intended use. This process must include the
4 means to determine whether the data fully meet standards and what to do if they do not.

5 The Uniform Federal Policy for Quality Assurance Project Plans (UFP-QAPP) provides
6 instructions for preparing Quality Assurance Project Plans (QAPPs) for any
7 environmental data collection operation (IDQTF 2005). A QAPP is a formal document
8 describing in detail the QA/QC, and other technical activities that must be implemented
9 to ensure that data and related analyses satisfy stated performance criteria, how
10 performance measures are verified and validated and how to proceed if there are any
11 limitations in the data that prevent attainment of the required level of accuracy.

12 The MRRP QAPP (see Appendix I) was developed to address system-wide and project-
13 specific environmental monitoring QA/QC, including data collection, analysis, and
14 archiving activities, throughout the entire AM cycle, activities which are summarized in
15 section 6.1. All agencies and contractors involved in environmental data acquisition
16 during MRRP implementation are required to adhere to the provisions of the QAPP. The
17 information presented in the QAPP (or referenced therein) serves as the basis of the
18 quality system for all monitoring activities conducted during MRRP implementation
19 and details QA/QC requirements, including establishing data quality objectives and
20 guidance for data management. Also included are procedures and references for
21 biological, hydrologic, geomorphic and other relevant sample collection, laboratory
22 methods, and data assessment protocols.

23 The QAPP will be updated and refined periodically to strengthen the QA program. All
24 agencies, contractors, etc., involved in environmental data acquisition during MRRP
25 implementation are required to adhere to the provisions of the QAPP. A biennial Quality
26 Assurance Review (QAR) will be conducted by an independent entity to provide MRRP
27 management and stakeholders with an assessment of the state of data quality for MRRP.
28 The goals of the QAR are to identify practices that contribute to data quality, identify
29 data quality problems and best management practices, report on the activities of the AM
30 Teams, and recommend improvements to the quality system for MRRP monitoring. As
31 such, when specific data quality issues are discussed in this report, a less-than-perfect
32 assessment is meant to identify an opportunity for continuous process improvement,
33 not failure.

34 **6.4.1 Basic Principles for Quality Assurance**

35 AM of the MRRP will require many decisions that will be made on the basis of
36 information available at that time. The following principles (consistent with the

1 principles described in section 6.1) will help ensure that those decisions are made using
2 the best information possible, and serve to guide the development of the QAPP and its
3 periodic review and improvement.

4 **Quality.** Information quality is integral to every step of the AM cycle. The AM Teams
5 should employ appropriate practices to ensure quality during the creation, collection,
6 maintenance and dissemination of data and other information. Any information used
7 for decision-making should be thoroughly reviewed by expert staff and appropriate
8 levels of management. Both internal and external review and approval policies and
9 procedures should ensure, to the extent practical, that disseminated information and
10 data are accurate and timely, appropriate for consumption, uncompromised and useful
11 to decision-makers, stakeholders and the public.

12 **Objectivity.** The MRRP AM Program relies upon information that is accurate, clear,
13 complete and unbiased both in its content and in its presentation. The relevant subject
14 matter experts and appropriate levels of management should review information before
15 it is disseminated, among other things, to evaluate whether the information is accurate,
16 reliable and unbiased, including an assessment of collection, generation, and analysis of
17 relevant information and data. The review also should consider the presentation of the
18 information to ensure that it is put in the proper context and presented in a clear,
19 complete and unbiased manner. The sources of data used in decision making should be
20 identified so that decision makers, stakeholders and the public can assess for itself the
21 objectivity of those sources. This includes adequate disclosure about underlying data
22 sources, quantitative methods of analysis and assumptions used, to facilitate
23 reproducibility of the information according to commonly accepted scientific or
24 statistical standards by qualified third parties. Periodic external reviews or audits of
25 information should be conducted to ensure that it is objective.

26 **Utility.** Information and the appropriate form and vehicle for its presentation and
27 dissemination should be evaluated by relevant subject matter experts, along with
28 appropriate levels of management, to ensure its usefulness to the intended purpose.
29 This includes ensuring that the information is organized, written, and summarized in a
30 manner that facilitates its understanding and use by the intended audience. The
31 information also should be reviewed to ensure its timeliness and continuing relevance
32 for the intended audience.

33 **Integrity.** The AM Program should ensure necessary precautions for information
34 security pursuant to the Computer Security Act of 1987, the Government Information
35 Security Reform Act of 2000 and the Security of Federal Automated Information
36 Resources, OMB Circular A-130 (February 8, 1996). The protective measures should

1 cover the following information resources: sensitive data, software, hardware, physical
2 facilities and telecommunications. The information security measures should assure
3 that the information system has a level of security that is commensurate with the risk
4 and magnitude of the harm that could result from the loss, misuse, unauthorized
5 disclosure or improper modification of the information contained in the system.
6 Information which should not be made public (e.g., the specific locations of bird nests or
7 sacred tribal sites) must be kept secure.

8

9 **6.4.2 Data Quality Objectives (DQOs)**

10 Data Quality Objectives (DQOs, described in section 6.1) define the type, quality, and
11 quantity of data needed to make defensible decisions when implementing the AMP.
12 They identify the requirements for a field investigation and the limits on tolerable error
13 rates. They also indicate the intended end use of the data, including decisions that may
14 be made based on the information generated.

15 Additional DQOs may be required for specific projects or studies not envisioned at the
16 time of developing the AMP, or for which the necessary information to develop DQOs
17 did not exist. In those cases, and when reviewing and updating existing DQOs as new
18 information becomes available, the AM Teams should rely upon the seven-step process
19 outlined in Guidance for the Data Quality Objective Process (EPA 2006), summarized in
20 section 6.1.1.1.

21 The DQO process has both qualitative and quantitative components. The
22 qualitative steps encourage logical and practical planning for environmental data
23 collection activities, while the quantitative steps use statistical methods to design a data
24 collection operation that will efficiently control the probability of making an incorrect
25 decision. Although the quantitative steps of the DQO process are important,
26 investigators and decision makers may choose not to apply statistics to every
27 environmental field investigation. In some cases, the team may utilize only the
28 qualitative steps of the DQO process during the investigation planning phases to
29 generate authoritative data.

30 **6.4.3 QAPP organization and content**

31 The QAPP has been prepared for use by entities involved with implementing the
32 environmental monitoring and assessment components of the MRRP. These include
33 program managers, project personnel, agency representatives and private consultants
34 involved in designing monitoring plans, preparing contractual statements of work for
35 monitoring activities, and reviewing or validating data. Contractors involved in data

- 1 gathering activities, such as field measurements, observations or examinations,
2 calibrations, and data analyses may also utilize the QAPP to determine program,
3 sampling, and analytical protocols and requirements.
- 4 The MRRP QAPP is a project-specific plan organized to address four basic elements, as
5 required by the Uniform Federal Policy (IDQTF 2005):
- 6 • Project Management and Objectives
7 • Measurement and Data Acquisition
8 • Assessment and Oversight
9 • Data Review
- 10 All QAPPs must address all elements detailed in the UFP-QAPP Manual (IDQTF 2005).
11 In some cases, certain elements do not apply to the MRRP. In those cases the
12 requirement is addressed with a simple statement of why the information is not
13 relevant. Although Appendix I is the QAPP for the MRRP, some of the requirements are
14 found elsewhere in the AMP or in other external documents. In those cases, the
15 information is cross referenced in the appendix and details the information in the plan
16 and its location.
- 17 **6.4.4 QAPP implementation responsibilities**
- 18 Each agency, contractor, consultant, and individual involved with MRRP monitoring
19 must share responsibility for maintaining knowledge of the QA/QC program and for
20 adhering to the procedures identified in the QAPP. However, the ultimate responsibility
21 for implementation of the QA/QC program rests with the ISP.
- 22 The ISP, working and coordinating with the various AM Teams, is charged with
23 implementation and oversight of the MRRP QA/QC program and will ensure that
24 monitoring adheres to the QAPP. The ISP is responsible for dealing with QA issues,
25 establishing a mechanism for distribution of quality system information and changes,
26 and ensuring data meet or exceed the DQOs of the AMP. Some of the ISP
27 responsibilities with respect to the AMP include the following:

- 28 • Developing and implementing data review criteria
29 • Conducting audits of field and laboratory activities
30 • Performing QA reviews of monitoring data
31 • Implementing laboratory and field performance evaluation (PE) programs to assess
32 consistency among entities involved in the data collection activities
33 • Producing biennial Quality Assessment Reports and submitting them to
34 management and MRRIC

- 1 • Developing Quality Management Plans for the AMP and associated annual quality
2 assessment reports
3 • Coordinating governmental and commercial laboratories to ensure adequate
4 training, coordination, and consistency in laboratory and field procedures
5 • Initiating/conducting systems audits, performance audits, and corrective actions
6 • Reviewing new and alternative methods and requests for sample modifications
7 • Conducting data verification, validation, and quality assessment as needed
8 • Coordinating training for these functions and making sure the guidelines are
9 followed and any deficiencies are corrected.
- 10 Standardized monitoring/data collection methodologies, sampling schemes, laboratory
11 analytical methods, and QA and reporting procedures for each of the monitoring
12 parameters will be agreed upon and used by all participating investigators in the
13 program for collecting, processing, and managing data. Any changes in methods during
14 the implementation of the plan, once approved, will be documented. The ISP will also
15 interact with the MRRP Management and MRRIC Work or Task Groups to review and
16 comment on all data-related technical specification; ensure that a proper data QA/QC
17 process will be in place, particularly for data acquisition contracts; and review contract
18 Statements of Work (SOWs) for monitoring.

19 **6.4.5 Alternative Procedures or Variances**

20 To maintain a level of standardization and consistency and to help ensure verifiable data
21 quality, adherence to QAPP provisions is critical. However, the intention of QAPP is not
22 to be restrictive, but rather to encourage agile responses to identified challenges, as well
23 as to stimulate the creation of new methods and innovations. Proper approvals,
24 including those of any regulatory agency, if deemed necessary by the ISP, are required
25 prior to implementing a variance from the QAPP. Variances may involve the use of
26 alternate laboratory or field procedures, QA/QC elements, and data validation or data
27 management procedures. Variances may be driven by project limitations, a need for
28 enhancements or improvements, such as better technology, or for experimental or
29 research purposes. The QAPP details processes that will be used for review and approval
30 of variances for water quality monitoring and analysis; alternate biological, ecological,
31 and hydrologic procedures; and remote sensing procedures and protocols. The ultimate
32 goal of the variance process is to ensure that the proposed alternative procedure or
33 method will produce data of a quality appropriate to the study's objectives, and
34 consistent with MRRP data gathering activities.
